Renesas Synergy™ Platform

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

6. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

Renesas Synergy Specific Information

If you are using NetX for the Renesas Synergy platform, please use the following information.

Customer Support Center

Page 12: For Renesas Synergy platform support, please contact Renesas directly:

Support: <https://renesas-synergy.com/support>

Installation and Use of NetX

Page 23: If you are using Renesas Synergy SSP and the e² studio ISDE, NetX will already be installed. You can ignore the NetX Installation section.

Product Distribution

Page 25: The NetX distribution installed with Renesas Synergy SSP does not include the readme_netx.txt and demo_netx.c files. Please ignore references to these files.

Driver Requests

Page 364-370: Following driver requests are not implemented in sf_el_nx (SSP)

1. Attach interface
 2. Detach interface
 3. Get link speed
 4. Get duplex type
 5. Get error count
 6. Get receive packet count
 7. Get transmit packet count
 8. Get allocation errors

About This Guide

This guide contains comprehensive information about NetX, the high-performance network stack from Express Logic.

It is intended for embedded real-time software developers familiar with basic networking concepts, the ThreadX RTOS, and the C programming language.

Organization

Chapter 1	Introduces NetX
Chapter 2	Gives the basic steps to install and use NetX with your ThreadX application.
Chapter 3	Provides a functional overview of the NetX system and basic information about the TCP/IP networking standards.
Chapter 4	Details the application's interface to NetX.
Chapter 5	Describes network drivers for NetX.
Appendix A	NetX Services
Appendix B	NetX Constants
Appendix C	NetX Data Types
Appendix D	BSD-Compatible Socket API

Appendix E	ASCII Chart
Index	Topic cross reference

Guide Conventions

Italics Typeface denotes book titles, emphasizes important words, and indicates variables.

Boldface Typeface denotes file names, key words, and further emphasizes important words and variables.

Information symbols draw attention to important or additional information that could affect performance or function.

Warning symbols draw attention to situations that developers should avoid because they could cause fatal errors.

NetX Data Types

In addition to the custom NetX control structure data types, there are several special data types that are used in NetX service call interfaces. These special data types map directly to data types of the underlying C compiler. This is done to ensure portability between different C compilers. The exact implementation is inherited from ThreadX and can be found in the ***tx_port.h*** file included in the ThreadX distribution.

The following is a list of NetX service call data types and their associated meanings:

UINT	Basic unsigned integer. This type must support 32-bit unsigned data; however, it is mapped to the most convenient unsigned data type.
ULONG	Unsigned long type. This type must support 32-bit unsigned data.
VOID	Almost always equivalent to the compiler's void type.
CHAR	Most often a standard 8-bit character type.

Additional data types are used within the NetX source. They are located in either the ***tx_port.h*** or ***nx_port.h*** files.

Customer Support Center

Latest Product Information

Visit the Express Logic web site and select the “Support” menu option to find the latest online support information, including information about the latest NetX product releases.

What We Need From You

To more efficiently resolve your support request, provide us with the following information in your email request:

1. A detailed description of the problem, including frequency of occurrence and whether it can be reliably reproduced.
2. A detailed description of any changes to the application and/or NetX that preceded the problem.
3. The contents of the **`_tx_version_id`** and **`_nx_version_id`** strings found in the **`tx_port.h`** and **`nx_port.h`** files of your distribution. These strings will provide us valuable information regarding your run-time environment.
4. The contents in RAM of the following ULONG variables:

`_tx_build_options`
`_nx_system_build_options1`
`_nx_system_build_options2`
`_nx_system_build_options3`

`_nx_system_build_options4`
`_nx_system_build_options5`

These variables will give us information on how your ThreadX and NetX libraries were built.

5. A trace buffer captured immediately after the problem was detected. This is accomplished by building the ThreadX and NetX libraries with **`TX_ENABLE_EVENT_TRACE`** and calling **`tx_trace_enable`** with the trace buffer information. Refer to the *TraceX User Guide* for details.

Where to Send Comments About This Guide

The staff at Express Logic is always striving to provide you with better products. To help us achieve this goal, email any comments and suggestions to the Customer Support Center at

support@expresslogic.com

Please enter “NetX User Guide” in the subject line.

Introduction to NetX

NetX is a high-performance real-time implementation of the TCP/IP standards designed exclusively for embedded ThreadX-based applications. This chapter contains an introduction to NetX and a description of its applications and benefits.

- NetX Unique Features 16
 - Piconet™ Architecture 16
 - Zero-copy Implementation 16
 - UDP Fast Path™ Technology 17
 - ANSI C Source Code 17
 - Not A Black Box 17
 - BSD-Compatible Socket API 18
- RFCs Supported by NetX 18
- Embedded Network Applications 19
 - Real-time Network Software 19
- NetX Benefits 19
 - Improved Responsiveness 19
 - Software Maintenance 20
 - Increased Throughput 20
 - Processor Isolation 20
 - Ease of Use 20
 - Improve Time to Market 20
- Protecting the Software Investment 21

NetX Unique Features

Unlike other TCP/IP implementations, NetX is designed to be versatile—easily scaling from small micro-controller-based applications to those that use powerful RISC and DSP processors. This is in sharp contrast to public domain or other commercial implementations originally intended for workstation environments but then squeezed into embedded designs.

Piconet™ Architecture

Underlying the superior scalability and performance of NetX is *Piconet*, a software architecture especially designed for embedded systems. Piconet architecture maximizes scalability by implementing NetX services as a C library. In this way, only those services actually used by the application are brought into the final runtime image. Hence, the actual size of NetX is completely determined by the application. For most applications, the instruction image requirements of NetX ranges between 5 KBytes and 30 KBytes in size.

NetX achieves superior network performance by layering internal component function calls only when it is absolutely necessary. In addition, much of NetX processing is done directly in-line, resulting in outstanding performance advantages over the workstation network software used in embedded designs in the past.

Zero-copy Implementation

NetX provides a packet-based, zero-copy implementation of TCP/IP. Zero copy means that data in the application's packet buffer are never copied inside NetX. This greatly improves performance and frees up valuable processor cycles

to the application, which is extremely important in embedded applications.

UDP Fast Path™ Technology

With *UDP Fast Path Technology*, NetX provides the fastest possible UDP processing. On the sending side, UDP processing—including the optional UDP checksum—is completely contained within the ***nx_udp_socket_send*** service. No additional function calls are made until the packet is ready to be sent via the internal NetX IP send routine. This routine is also flat (i.e., its function call nesting is minimal) so the packet is quickly dispatched to the application's network driver. When the UDP packet is received, the NetX packet-receive processing places the packet directly on the appropriate UDP socket's receive queue or gives it to the first thread suspended waiting for a receive packet from the UDP socket's receive queue. No additional ThreadX context switches are necessary.

ANSI C Source Code

NetX is written completely in ANSI C and is portable immediately to virtually any processor architecture that has an ANSI C compiler and ThreadX support.

Not A Black Box

Most distributions of NetX include the complete C source code. This eliminates the “black-box” problems that occur with many commercial network stacks. By using NetX, applications developers can see exactly what the network stack is doing—there are no mysteries!

Having the source code also allows for application-specific modifications. Although not recommended, it is certainly beneficial to have the ability to modify the network stack if it is required.

These features are especially comforting to developers accustomed to working with in-house or public domain network stacks. They expect to have source code and the ability to modify it. NetX is the ultimate network software for such developers.

**BSD-Compatible
Socket API**

For legacy applications, NetX also provides a BSD-compatible socket interface that makes calls to the high-performance NetX API underneath. This helps in migrating existing network application code to NetX.

RFCs Supported by NetX

NetX support of RFCs describing basic network protocols includes but is not limited to the following network protocols. NetX follows all general recommendations and basic requirements within the constraints of a real-time operating system with small memory footprint and efficient execution.

RFC	Description
RFC 1112	Host Extensions for IP Multicasting (IGMPv1)
RFC 1122	Requirements for Internet Hosts - Communication Layers
RFC 2236	Internet Group Management Protocol, Version 2
RFC 768	User Datagram Protocol (UDP)
RFC 791	Internet Protocol (IP)
RFC 792	Internet Control Message Protocol (ICMP)
RFC 793	Transmission Control Protocol (TCP)
RFC 826	Ethernet Address Resolution Protocol (ARP)
RFC 903	Reverse Address Resolution Protocol (RARP)

Embedded Network Applications

Embedded network applications are applications that need network access and execute on microprocessors hidden inside products such as cellular phones, communication equipment, automotive engines, laser printers, medical devices, and so forth. Such applications almost always have some memory and performance constraints. Another distinction of embedded network applications is that their software and hardware have a dedicated purpose.

Real-time Network Software

Basically, network software that must perform its processing within an exact period of time is called *real-time network* software, and when time constraints are imposed on network applications, they are classified as real-time applications. Embedded network applications are almost always real-time because of their inherent interaction with the external world.

NetX Benefits

The primary benefits of using NetX for embedded applications are high-speed Internet connectivity and very small memory requirements. NetX is also completely integrated with the high-performance, multitasking ThreadX real-time operating system.

Improved Responsiveness

The high-performance NetX protocol stack enables embedded network applications to respond faster than ever before. This is especially important for embedded applications that either have a significant

volume of network traffic or stringent processing requirements on a single packet.

Software Maintenance

Using NetX allows developers to easily partition the network aspects of their embedded application. This partitioning makes the entire development process easy and significantly enhances future software maintenance.

Increased Throughput

NetX provides the highest-performance networking available, which is achieved by minimal packet processing overhead. This also enables increased throughput.

Processor Isolation

NetX provides a robust, processor-independent interface between the application and the underlying processor and network hardware. This allows developers to concentrate on the network aspects of the application rather than spending extra time dealing with hardware issues directly affecting networking.

Ease of Use

NetX is designed with the application developer in mind. The NetX architecture and service call interface are easy to understand. As a result, NetX developers can quickly use its advanced features.

Improve Time to Market

The powerful features of NetX accelerate the software development process. NetX abstracts most processor and network hardware issues, thereby removing these concerns from a majority of application network-specific areas. This, coupled with the ease-of-use and advanced feature set, result in a faster time to market!

Protecting the Software Investment

NetX is written exclusively in ANSI C and is fully integrated with the ThreadX real-time operating system. This means NetX applications are instantly portable to all ThreadX supported processors. Better still, a completely new processor architecture can be supported with ThreadX in a matter of weeks. As a result, using NetX ensures the application's migration path and protects the original development investment.

Installation and Use of NetX

This chapter contains a description of various issues related to installation, setup, and use of the high-performance network stack NetX, including the following:

- Host Considerations 24
- Target Considerations 25
- Product Distribution 25
- NetX Installation 26
- Using NetX 26
- Troubleshooting 27
- Configuration Options 28
 - System Configuration Options 28
 - ARP Configuration Options 30
 - ICMP Configuration Options 31
 - IGMP Configuration Options 31
 - IP Configuration Options 31
 - Packet Configuration Options 33
 - RARP Configuration Options 33
 - TCP Configuration Options 33
 - UDP Configuration Options 37
- NetX Version ID 37

Host Considerations

Embedded development is usually performed on Windows or Linux (Unix) host computers. After the application is compiled, linked, and the executable is generated on the host, it is downloaded to the target hardware for execution.

Usually the target download is done from within the development tool's debugger. After download, the debugger is responsible for providing target execution control (go, halt, breakpoint, etc.) as well as access to memory and processor registers.

Most development tool debuggers communicate with the target hardware via on-chip debug (OCD) connections such as JTAG (IEEE 1149.1) and Background Debug Mode (BDM). Debuggers also communicate with target hardware through In-Circuit Emulation (ICE) connections. Both OCD and ICE connections provide robust solutions with minimal intrusion on the target resident software.

As for resources used on the host, the source code for NetX is delivered in ASCII format and requires approximately 1 Mbytes of space on the host computer's hard disk.

*Review the supplied **readme_netx.txt** file for additional host system considerations and options.*

Target Considerations

NetX requires between 5 KBytes and 45 KBytes of Read-Only Memory (ROM) on the target. Another 1 to 5KBytes of the target's Random Access Memory (RAM) are required for the NetX thread stack and other global data structures.

In addition, NetX requires the use of two ThreadX timer objects and one ThreadX mutex object. These facilities are used for periodic processing needs and thread protection inside the NetX protocol stack.

Product Distribution

The exact content of the distribution disk depends on the target processor, development tools, and the NetX package purchased. However, the following is a list of several important files that are common to most product distributions:

NetX_Express_Startup.pdf

PDF that provides a simple, four-step procedure to get NetX running on a specific target processor/board and specific development tools.

readme_netx.txt

Text file containing specific information about the NetX port, including information about the target processor and the development tools.

nx_api.h

C header file containing all system equates, data structures, and service prototypes.

nx_port.h	C header file containing all development-tool and target-specific data definitions and structures.
demo_netx.c	C file containing a small demo application.
nx.a (or nx.lib)	Binary version of the NetX C library that is distributed with the <i>standard</i> package.

NetX Installation

Installation of NetX is straightforward. Refer to the ***NetX_Express_Startup.pdf*** file and the ***readme_netx.txt*** file for specific information on installing NetX for your specific environment.

Be sure to back up the NetX distribution disk and store it in a safe location.

*Application software needs access to the NetX library file (usually **nx.a** or **nx.lib**) and the C include files **nx_api.h**, and **nx_port.h**. This is accomplished either by setting the appropriate path for the development tools or by copying these files into the application development area.*

Using NetX

Using NetX is easy. Basically, the application code must include **nx_api.h** during compilation and link with the NetX library **nx.a** (or **nx.lib**).

The following are the four easy steps required to build a NetX application:

- Step 1:** Include the ***nx_api.h*** file in all application files that use NetX services or data structures.
- Step 2:** Initialize the NetX system by calling ***nx_system_initialize*** from the ***tx_application_define*** function or an application thread.
- Step 3:** Create an IP instance, enable the Address Resolution Protocol (ARP), if necessary, and any sockets after ***nx_system_initialize*** is called.
- Step 4:** Compile application source and link with the NetX runtime library ***nx.a*** (or ***nx.lib***). The resulting image can be downloaded to the target and executed!

Troubleshooting

Each NetX port is delivered with one or more demonstrations that execute on an actual network or via a simulated network driver. It is always a good idea to get the demonstration system running first.

See the ***readme_netx.txt*** file supplied with the distribution for more specific details regarding the demonstration system.

If the demonstration system does not run properly, perform the following operations to narrow the problem:

1. Determine how much of the demonstration is running.
2. Increase stack sizes in any new application threads.
3. Recompile the NetX library with the appropriate debug options listed in the configuration option section.

4. Examine the NX_IP structure to see if packets are being sent or received.
5. Examine the default packet pool to see if there are available packets.
6. Ensure the network driver is supplying ARP and IP packets with its headers on 4-byte boundaries for applications requiring IP connectivity.
7. Temporarily bypass any recent changes to see if the problem disappears or changes. Such information should prove useful to Express Logic support engineers.

Follow the procedures outlined in the “What We Need From You” on page 12 to send the information gathered from the troubleshooting steps.

Configuration Options

There are several configuration options when building the NetX library and the application using NetX. The configuration options can be defined in the application source, on the command line, or within the ***nx_user.h*** include file, unless otherwise specified.

*Options defined in ***nx_user.h*** are applied only if the application and NetX library are built with ***NX_INCLUDE_USER_DEFINE_FILE*** defined.*

Review the ***readme_netx_generic.txt*** file for additional options for your specific version of NetX. The following sections list the configuration options available in NetX.

System Configuration Options

NX_DEBUG

Defined, enables the optional print debug information available from the RAM Ethernet network driver.

NX_DISABLE_ERROR_CHECKING

Defined, removes the basic NetX error checking API and improves performance. API return codes not affected by disabling error checking are listed in bold typeface in the API definition. This define is typically used after the application is debugged sufficiently and its use improves performance and decreases code size.

NX_DRIVER_DEFERRED_PROCESSING

Defined, enables deferred network driver packet handling. This allows the network driver to place a packet on the IP instance and have the real processing routine called from the NetX internal IP helper thread.

NX_ENABLE_EXTENDED_NOTIFY_SUPPORT

Defined, enables more callback hooks in the stack. These callback functions are used by the BSD wrapper layer. By default this option is not defined.

NX_ENABLE_SOURCE_ADDRESS_CHECK

Defined, enables the source address of incoming packet to be checked. By default this option is disabled.

NX_LITTLE_ENDIAN

Defined, performs the necessary byte swapping on little endian environments to ensure the protocol headers are in proper big endian format. Note the default is typically setup in ***nx_port.h***.

NX_MAX_PHYSICAL_INTERFACES

Specifies the total number of physical network interfaces on the device. The default value is 1 and is defined in ***nx_api.h***; a device must have at least one physical interface. Note this does not include the loopback interface.

NX_PHYSICAL_HEADER

Specifies the size in bytes of the physical header of the frame. The default value is 16 (based on a typical 14-byte Ethernet frame aligned to 32-bit boundary) and is defined in ***nx_api.h***. The application can override the default by defining the value before ***nx_api.h*** is included, such as in ***nx_user.h***.

ARP Configuration Options

`NX_ARP_DEFEND_BY_REPLY`

Defined, allows NetX to defend its IP address by sending an ARP response.

`NX_ARP_DEFEND_INTERVAL`

Defines the interval, in seconds, the ARP module sends out the next defend packet in response to an incoming ARP message that indicates an address in conflict.

`NX_ARP_DISABLE_AUTO_ARP_ENTRY`

Renamed to **`NX_DISABLE_ARP_AUTO_ENTRY`**. Although it is still being supported, new designs are encouraged to use **`NX_DISABLE_ARP_AUTO_ENTRY`**.

`NX_ARP_EXPIRATION_RATE`

Specifies the number of seconds ARP entries remain valid. The default value of zero disables expiration or aging of ARP entries and is defined in **`nx_api.h`**. The application can override the default by defining the value before **`nx_api.h`** is included.

`NX_ARP_MAC_CHANGE_NOTIFICATION_ENABLE`

Renamed to **`NX_ENABLE_ARP_MAC_CHANGE_NOTIFICATION`**. Although it is still being supported, new designs are encouraged to use **`NX_ENABLE_ARP_MAC_CHANGE_NOTIFICATION`**.

`NX_ARP_MAX_QUEUE_DEPTH`

Specifies the maximum number of packets that can be queued while waiting for an ARP response. The default value is 4 and is defined in **`nx_api.h`**.

`NX_ARP_MAXIMUM_RETRIES`

Specifies the maximum number of ARP retries made without an ARP response. The default value is 18 and is defined in **`nx_api.h`**. The application can override the default by defining the value before **`nx_api.h`** is included.

`NX_ARP_UPDATE_RATE`

Specifies the number of seconds between ARP retries. The default value is 10, which represents 10 seconds, and is defined in **`nx_api.h`**. The application can override the default by defining the value before **`nx_api.h`** is included.

NX_DISABLE_ARP_AUTO_ENTRY

Defined, disables entering ARP request information in the ARP cache.

NX_DISABLE_ARP_INFO

Defined, disables ARP information gathering.

NX_ENABLE_ARP_MAC_CHANGE_NOTIFICATION

Defined, allows ARP to invoke a callback notify function on detecting the MAC address is updated.

ICMP Configuration Options

NX_DISABLE_ICMP_INFO

Defined, disables ICMP information gathering.

NX_DISABLE_ICMP_RX_CHECKSUM

Defined, disables both ICMP checksum computation on received ICMP packets. This option is useful when the network interface driver is able to verify the ICMP checksum, and the application does not use the IP fragmentation feature. By default this option is not defined.

NX_DISABLE_ICMP_TX_CHECKSUM

Defined, disables both ICMP checksum computation on transmitted ICMP packets. This option is useful where the network interface driver is able to compute the ICMP checksum, and the application does not use the IP fragmentation feature. By default this option is not defined.

IGMP Configuration Options

NX_DISABLE_IGMP_INFO

Defined, disables IGMP information gathering.

NX_DISABLE_IGMPV2

Defined, disables IGMPv2 support, and NetX supports IGMPv1 only. By default this option is not set and is defined in ***nx_api.h***.

NX_MAX_MULTICAST_GROUPS

Specifies the maximum number of multicast groups that can be joined. The default value is 7 and is defined in ***nx_api.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

IP Configuration Options

NX_DISABLE_FRAGMENTATION

Defined, disables IP fragmentation and reassembly logic.

<code>NX_DISABLE_IP_INFO</code>	Defined, disables IP information gathering.
<code>NX_DISABLE_IP_RX_CHECKSUM</code>	Defined, disables checksum logic on received IP packets. This is useful if the network device is able to verify the IP header checksum, and the application does not expect to use IP fragmentation.
<code>NX_DISABLE_IP_TX_CHECKSUM</code>	Defined, disables checksum logic on IP packets sent. This is useful in situations in which the underlying network device is capable of generating the IP header checksum, and the application does not expect to use IP fragmentation.
<code>NX_DISABLE_LOOPBACK_INTERFACE</code>	Defined, disables NetX support for the loopback interface.
<code>NX_DISABLE_RX_SIZE_CHECKING</code>	Defined, disables the size checking on received packets.
<code>NX_ENABLE_IP_STATIC_ROUTING</code>	Defined, enables IP static routing in which a destination address can be assigned a specific next hop address. By default IP static routing is disabled.
<code>NX_IP_PERIODIC_RATE</code>	Defined, specifies the number of ThreadX timer ticks in one second. The default value is derived from the ThreadX symbol <i>TX_TIMER_TICKS_PER_SECOND</i> , which by default is set to 100 (10ms timer). Applications shall exercise caution when modifying this value, as the rest of the NetX modules derive timing information from <i>NX_IP_PERIODIC_RATE</i> .
<code>NX_IP_ROUTING_TABLE_SIZE</code>	Defined, sets the maximum number of entries in the IP static routing table, which is a list of an outgoing interface and the next hop addresses for a given destination address. The default value is 8 and is defined in <i>nx_api.h</i> . This symbol is used only if <i>NX_ENABLE_IP_STATIC_ROUTING</i> is defined.

Packet Configuration Options

`NX_DISABLE_PACKET_INFO`

Defined, disables packet pool information gathering.

`NX_PACKET_HEADER_PAD`

Defined, enables padding towards the end of the `NX_PACKET` control block. The number of ULONG words to pad is defined by **`NX_PACKET_HEADER_PAD_SIZE`**.

`NX_PACKET_HEADER_PAD_SIZE`

Sets the number of ULONG words to be padded to the `NX_PACKET` structure, allowing the packet payload area to start at the desired alignment. This feature is useful when receive buffer descriptors point directly into `NX_PACKET` payload area, and the network interface receive logic or the cache operation logic expects the buffer starting address to meet certain alignment requirements. This value becomes valid only when **`NX_PACKET_HEADER_PAD`** is defined.

RARP Configuration Options

`NX_DISABLE_RARP_INFO` Defined, disables RARP information gathering.

TCP Configuration Options

`NX_DISABLE_RESET_DISCONNECT`

Defined, disables the reset processing during disconnect when the timeout value supplied is specified as **`NX_NO_WAIT`**.

`NX_DISABLE_TCP_INFO` Defined, disables TCP information gathering.

`NX_DISABLE_TCP_RX_CHECKSUM`

Defined, disables checksum logic on received TCP packets. This is only useful in situations in which the link-layer has reliable checksum or CRC processing, or the interface driver is able to verify TCP checksum in hardware.

`NX_DISABLE_TCP_TX_CHECKSUM`

Defined, disables checksum logic for sending TCP packets. This is only useful in situations in which the receiving

network node has received TCP checksum logic disabled or the underlying network driver is capable of generating TCP checksum.

`NX_ENABLE_TCP_KEEPALIVE`

Defined, enables the optional TCP keepalive timer. The default settings is not enabled.

`NX_ENABLE_TCP_MSS_CHECKING`

Defined, enables the verification of minimum peer MSS before accepting a TCP connection. To use this feature, the symbol **`NX_ENABLE_TCP_MSS_MINIMUM`** must be defined. By default, this option is not enabled.

`NX_ENABLE_TCP_WINDOW_SCALING`

Enables the window scaling option for TCP applications. If defined, window scaling option is negotiated during TCP connection phase, and the application is able to specify a window size larger than 64K. The default setting is not enabled (not defined).

`NX_MAX_LISTEN_REQUESTS`

Specifies the maximum number of server listen requests. The default value is 10 and is defined in **`nx_api.h`**. The application can override the default by defining the value before **`nx_api.h`** is included.

`NX_TCP_ACK EVERY N PACKETS`

Specifies the number of TCP packets to receive before sending an ACK. Note if **`NX_TCP_IMMEDIATE_ACK`** is enabled but **`NX_TCP_ACK EVERY N PACKETS`** is not, this value is automatically set to 1 for backward compatibility.

`NX_TCP_ACK_TIMER_RATE`

Specifies how the number of system ticks (`NX_IP_PERIODIC_RATE`) is divided to calculate the timer rate for the TCP delayed ACK processing. The default value is 5, which represents 200ms, and is defined in **`nx_tcp.h`**. The application can override the default by defining the value before **`nx_api.h`** is included.

`NX_TCP_ENABLE_KEEPALIVE`

Renamed to **`NX_ENABLE_TCP_KEEPALIVE`**. Although it is still being supported, new designs are encouraged to use **`NX_ENABLE_TCP_KEEPALIVE`**.

NX_TCP_ENABLE_WINDOW_SCALING

Renamed to ***NX_ENABLE_TCP_WINDOW_SCALING***.

Although it is still being supported, new designs are encouraged to use ***NX_ENABLE_TCP_WINDOW_SCALING***.

NX_TCP_FAST_TIMER_RATE

Specifies how the number of NetX internal ticks (NX_IP_PERIODIC_RATE) is divided to calculate the fast TCP timer rate. The fast TCP timer is used to drive the various TCP timers, including the delayed ACK timer. The default value is 10, which represents 100ms assuming the ThreadX timer is running at 10ms. This value is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_IMMEDIATE_ACK

Defined, enables the optional TCP immediate ACK response processing. Defining this symbol is equivalent to defining ***NX_TCP_ACK EVERY_N PACKETS*** to be 1.

NX_TCP_KEEPALIVE_INITIAL

Specifies the number of seconds of inactivity before the keepalive timer activates. The default value is 7200, which represents 2 hours, and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_KEEPALIVE_RETRIES

Specifies how many keepalive retries are allowed before the connection is deemed broken. The default value is 10, which represents 10 retries, and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_KEEPALIVE_RETRY

Specifies the number of seconds between retries of the keepalive timer assuming the other side of the connection is not responding. The default value is 75, which represents 75 seconds between retries, and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_MAX_OUT_OF_ORDER_PACKETS

Symbol that defines the maximum number of out-of-order TCP packets can be kept in the TCP socket receive queue. This symbol can be used to limit the number of packets queued in

the TCP receive socket, preventing the packet pool from being starved. By default this symbol is not defined, thus there is no limit on the number of out of order packets being queued in the TCP socket.

NX_TCP_MAXIMUM_RETRIES

Specifies how many data transmit retries are allowed before the connection is deemed broken. The default value is 10, which represents 10 retries, and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_MAXIMUM_TX_QUEUE

Specifies the maximum depth of the TCP transmit queue before TCP send requests are suspended or rejected. The default value is 20, which means that a maximum of 20 packets can be in the transmit queue at any given time. Note packets stay in the transmit queue until an ACK that covers some or all of the packet data is received from the other side of the connection. This constant is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_MSS_CHECKING_ENABLED

Renamed to ***NX_ENABLE_TCP_MSS_CHECKING***. Although it is still being supported, new designs are encouraged to use ***NX_ENABLE_TCP_MSS_CHECKING***.

NX_TCP_MSS_MINIMUM

Symbol that defines the minimal MSS value NetX TCP module accepts. This feature is enabled by ***NX_ENABLE_TCP_MSS_CHECK***.

NX_TCP_RETRY_SHIFT

Specifies how the retransmit timeout period changes between retries. If this value is 0, the initial retransmit timeout is the same as subsequent retransmit timeouts. If this value is 1, each successive retransmit is twice as long. If this value is 2, each subsequent retransmit timeout is four times as long. The default value is 0 and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

NX_TCP_TRANSMIT_TIMER_RATE

Specifies how the number of system ticks (***NX_IP_PERIODIC_RATE***) is divided to calculate the timer

rate for the TCP transmit retry processing. The default value is 1, which represents 1 second, and is defined in ***nx_tcp.h***. The application can override the default by defining the value before ***nx_api.h*** is included.

UDP Configuration Options

NX_DISABLE_UDP_INFO Defined, disables UDP information gathering.

NX_DISABLE_UDP_RX_CHECKSUM

Defined, disables the UDP checksum computation on incoming UDP packets. This is useful if the network interface driver is able to verify UDP header checksum in hardware, and the application does not enable IP fragmentation logic.

NX_DISABLE_UDP_TX_CHECKSUM

Defined, disables the UDP checksum computation on outgoing UDP packets. This is useful if the network interface driver is able to compute UDP header checksum and insert the value in the IP head before transmitting the data, and the application does not enable IP fragmentation logic.

NetX Version ID

The current version of NetX is available to both the user and the application software during runtime. The programmer can find the NetX version in the ***readme_netx_generic.txt*** file. This file also contains a version history of the corresponding port. Application software can obtain the NetX version by examining the global string ***_nx_version_id*** in ***nx_port.h***.

Application software can also obtain release information from the constants shown below defined in ***nx_api.h***.

These constants identify the current product release by name and the product major and minor version.

```
#define EL_PRODUCT_NETX
#define NETX_MAJOR_VERSION
#define NETX_MINOR_VERSION
```

Functional Components of NetX

Execution Overview

There are five types of program execution within a NetX application: initialization, application interface calls, internal IP thread, IP periodic timers, and the network driver.

NetX assumes the existence of ThreadX and depends on its thread execution, suspension, periodic timers, and mutual exclusion facilities.

Initialization

The service ***nx_system_initialize*** must be called before any other NetX service is called. System initialization can be called either from the ThreadX ***tx_application_define*** routine or from application threads.

After ***nx_system_initialize*** returns, the system is ready to create packet pools and IP instances. Because creating an IP instance requires a default packet pool, at least one NetX packet pool must exist prior to creating an IP instance. Creating packet pools and IP instances are allowed from the ThreadX initialization function ***tx_application_define*** and from application threads.

Internally, creating an IP instance is accomplished in two parts: The first part is done within the context of the caller, either from ***tx_application_define*** or from an application thread's context. This includes setting up the IP data structure and creating various IP resources, including the internal IP thread. The second part is performed during the initial execution from the internal IP thread. This is where the network driver, supplied during the first part of IP creation, is first called. Calling the network driver from the internal IP thread enables the driver to perform I/O and suspend during its initialization processing. When the network driver returns from its initialization processing, the IP creation is complete.

The NetX service ***nx_ip_status_check*** is available to obtain information on the IP instance and its primary interface status. Such status information includes whether or not the link is initialized, enabled and IP address is resolved. This information is used to synchronize application threads needing to use a newly created IP instance. For multihome systems, see “Multihome Support” on page 46.

nx_ip_interface_status_check is available to obtain information on the specified interface.

Application Interface Calls

Calls from the application are largely made from application threads running under the ThreadX RTOS. However, some initialization, create, and enable services may be called from ***tx_application_define***. The “Allowed From” sections in Chapter 4 indicate from which each NetX service can be called.

For the most part, processing intensive activities such as computing checksums is done within the calling thread's context—without blocking access of other threads to the IP instance. For example, on transmission, the UDP checksum calculation is performed inside the ***nx_udp_socket_send*** service, prior to calling the underlying IP send function. On a received packet, the UDP checksum is calculated in the ***nx_udp_socket_receive*** service, executed in the context of the application thread. This helps prevent stalling network requests of higher-priority threads because of processing intensive checksum computation in lower-priority threads.

Values, such as IP addresses and port numbers, are passed to APIs in host byte order. Internally these values are stored in host byte order as well. This allows developers to easily view the values via a debugger. When these values are programmed into a

frame for transmission, they are converted to network byte order.

Internal IP Thread

As mentioned, each IP instance in NetX has its own thread. The priority and stack size of the internal IP thread is defined in the ***nx_ip_create*** service. The internal IP thread is created in a ready-to-execute mode. If the IP thread has a higher priority than the calling thread, preemption may occur inside the IP create call.

The entry point of the internal IP thread is at the internal function ***_nx_ip_thread_entry***. When started, the internal IP thread first completes network driver initialization, which consists of making three calls to the application-specific network driver. The first call is to attach the network driver to the IP instance, followed by an initialization call, which allows the network driver to go through the initialization process. After the network driver returns from initialization (it may suspend while waiting for the hardware to be properly set up), the internal IP thread calls the network driver again to enable the link. After the network driver returns from the link enable call, the internal IP thread enters a forever loop checking for various events that need processing for this IP instance. Events processed in this loop include deferred IP packet reception, IP packet fragment assembly, ICMP ping processing, IGMP processing, TCP packet queue processing, TCP periodic processing, IP fragment assembly timeouts, and IGMP periodic processing. Events also include address resolution activities: ARP packet processing and ARP periodic processing in the IP network.

The NetX callback functions, including listen and disconnect callbacks, are called from the internal IP thread—not the original calling thread. The

application must take care not to suspend inside any NetX callback function.

IP Periodic Timers

There are two ThreadX periodic timers used for each IP instance. The first one is a one-second timer for ARP, IGMP, TCP timeout, and it also drives IP fragment reassemble processing. The second timer is a 100ms timer to drive the TCP retransmission timeout.

Network Driver

Each IP instance in NetX has a primary interface, which is identified by its device driver specified in the ***nx_ip_create*** service. The network driver is responsible for handling various NetX requests, including packet transmission, packet reception, and requests for status and control.

For a multi-home system, the IP instance has multiple interfaces, each with an associated network driver that performs these tasks for the respective interface.

The network driver must also handle asynchronous events occurring on the media. Asynchronous events from the media include packet reception, packet transmission completion, and status changes. NetX provides the network driver with several access functions to handle various events. These functions are designed to be called from the interrupt service routine portion of the network driver. For IP networks, the network driver should forward all ARP packets received to the ***_nx_arp_packet_deferred_receive*** internal function. All RARP packets should be forwarded to ***_nx_rarp_packet_deferred_receive*** internal function. There are two options for IP packets. If fast dispatch of IP packets is required, incoming IP packets should be forwarded to ***_nx_ip_packet_receive*** for immediate processing.

This greatly improves NetX performance in handling IP packets. Otherwise, forwarding IP packets to **`_nx_ip_packet_deferred_receive`** should be done. This service places the IP packet in the deferred processing queue where it is then handled by the internal IP thread, which results in the least amount of ISR processing time.

The network driver can also defer interrupt processing to run out of the context of the IP thread. In this mode, the ISR shall save the necessary information, call the internal function **`_nx_ip_driver_deferred_processing`**, and acknowledge the interrupt controller. This service notifies IP thread to schedule a callback to the device driver to complete the process of the event that causes the interrupt.

Some network controllers are capable of performing TCP/IP header checksum computation and validation in hardware, without taking up valuable CPU resources. To take advantage of the hardware capability feature, NetX provides options to enable or disable various software checksum computation at compilation time, as well as turning on or off checksum computation at run time. See “NetX Network Drivers” on page 353 for more detailed information on writing NetX network drivers.

Multihome Support

NetX supports systems connected to multiple physical devices using a single IP instance. Each physical interface is assigned to an interface control block in the IP instance. Applications wishing to use a multihome system must define the value for **`NX_MAX_PHYSICAL_INTERFACES`** to the number of physical devices attached to the system, and rebuild NetX library. By default

NX_MAX_PHYSICAL_INTERFACES is set to one, creating one interface control block in the IP instance.

The NetX application creates a single IP instance for the primary device using the ***nx_ip_create*** service. For each additional network devices, the application attaches the device to the IP instance using the ***nx_ip_interface_attach*** service.

Each network interface structure contains a subset of network information about the network interface that is contained in the IP control block, including interface IP address, subnet mask, IP MTU size, and MAC-layer address information.

NetX with multihome support is backward compatible with earlier versions of NetX. Services that do not take explicit interface information default to the primary network device.

The primary interface has index zero in the IP instance list. Each subsequent device attached to the IP instance is assigned the next index.

All upper layer protocol services for which the IP instance is enabled, including TCP, UDP, ICMP, and IGMP, are available to all the attached devices.

In most cases, NetX can determine the best source address to use when transmitting a packet. The source address selection is based on the destination address. NetX services are added to allow applications to specify a specific source address to use, in cases where the most suitable one cannot be determined by the destination address. An example would be in a multihome system, an application needs to send a packet to an IP broadcast or multicast destination addresses.

Services specifically for developing multihome applications include the following:

```

nx_igmp_multicast_interface_join
nx_ip_driver_interface_direct_command
nx_ip_interface_address_get
nx_ip_interface_address_set
nx_ip_interface_attach
nx_ip_interface_info_get
nx_ip_interface_status_check
nx_ip_raw_packet_interface_send
nx_udp_socket_interface_send

```

These services are explained in greater detail in “Description of NetX Services” on page 107.

Loopback Interface

The loopback interface is a special network interface without an physical link attached to. The loopback interface allows applications to communicate using the IP loopback address 127.0.0.1

To utilize a logical loopback interface, ensure the configurable option

NX_DISABLE_LOOPBACK_INTERFACE is not set.

Interface Control Blocks

The number of interface control blocks in the IP instance is the number of physical interfaces (defined by ***NX_MAX_PHYSICAL_INTERFACES***) plus the loopback interface if it is enabled. The total number of interfaces is defined in ***NX_MAX_IP_INTERFACES***.

Protocol Layering

The TCP/IP implemented by NetX is a layered protocol, which means more complex protocols are built on top of simpler underlying protocols. In TCP/IP, the lowest layer protocol is at the *link level* and is handled by the network driver. This level is typically

targeted towards Ethernet, but it could also be fiber, serial, or virtually any physical media.

On top of the link layer is the *network layer*. In TCP/IP, this is the IP, which is basically responsible for sending and receiving simple packets—in a best-effort manner—across the network. Management-type protocols like ICMP and IGMP are typically also categorized as network layers, even though they rely on IP for sending and receiving.

The *transport layer* rests on top of the network layer. This layer is responsible for managing the flow of data between hosts on the network. There are two types of transport services supported by NetX: UDP and TCP. UDP services provide best-effort sending and receiving of data between two hosts in a connectionless manner, while TCP provides reliable connection-oriented service between two host entities.

This layering is reflected in the actual network data packets. Each layer in TCP/IP contains a block of information called a header. This technique of surrounding data (and possibly protocol information) with a header is typically called data encapsulation. Figure 1 shows an example of NetX layering and Figure 2 shows the resulting data encapsulation for UDP data being sent.

Packet Pools

Allocating packets in a fast and deterministic manner is always a challenge in real-time networking applications. With this in mind, NetX provides the ability to create and manage multiple pools of fixed-size network packets.

FIGURE 1. Protocol Layering

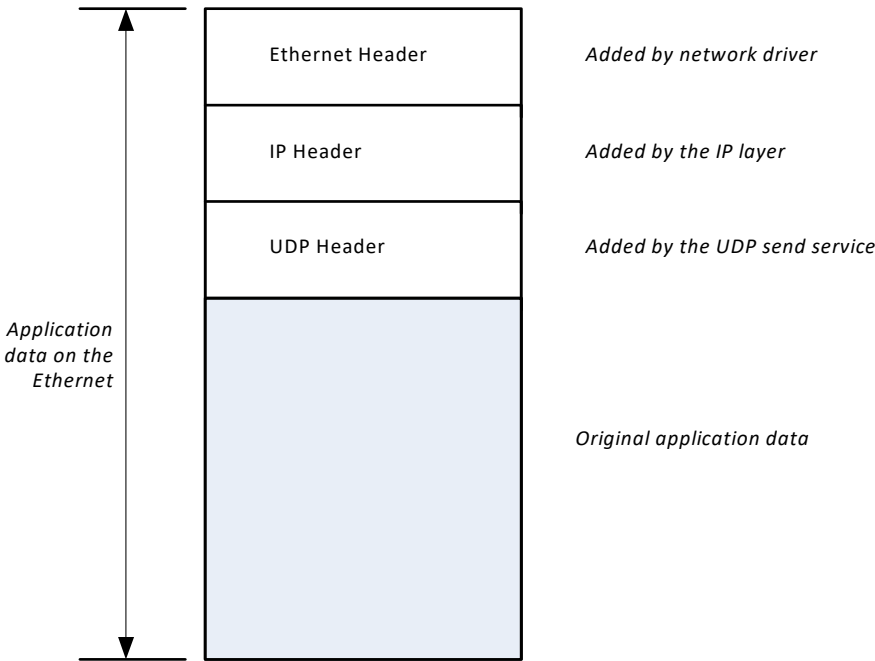

FIGURE 2. UDP Data Encapsulation

Because NetX packet pools consist of fixed-size memory blocks, there are never any internal fragmentation problems. Of course, fragmentation causes behavior that is inherently nondeterministic. In addition, the time required to allocate and free a NetX packet amounts to simple linked-list manipulation. Furthermore, packet allocation and deallocation is done at the head of the available list. This provides the fastest possible linked list processing.

Lack of flexibility is typically the main drawback of fixed-size packet pools. Determining the optimal packet payload size that also handles the worst-case incoming packet is a difficult task. NetX packets address this problem with an optional feature called packet chaining. An actual network packet can be made of one or more NetX packets linked together. In addition, the packet header maintains a pointer to the top of the packet. As additional protocols are added, this pointer is simply moved backwards and the new header is written directly in front of the data. Without the flexible packet technology, the stack would have to allocate another buffer and copy the data into a new buffer with the new header, which is processing intensive.

Since each packet payload size is fixed for a given packet pool, application data larger than the payload size would require multiple packets chained together. When filling a packet with user data, the application shall use the service ***nx_packet_data_append***. This service moves application data into a packet. In situations where a packet is not enough to hold user data, additional packets are allocated to store user data. To use packet chaining, the driver must be able to receive into or transmit from chained packets.

Each NetX packet memory pool is a public resource. NetX places no constraints on how packet pools are used.

Packet Pool Memory Area

The memory area for the packet pool is specified during creation. Like other memory areas for ThreadX and NetX objects, it can be located anywhere in the target's address space.

This is an important feature because of the considerable flexibility it gives the application. For example, suppose that a communication product has a high-speed memory area for network buffers. This memory area is easily utilized by making it into a NetX packet memory pool.

Creating Packet Pools

Packet pools are created either during initialization or during runtime by application threads. There are no limits on the number of packet memory pools in a NetX application.

Packet Header NX_PACKET

By default, NetX places the packet header immediately before the packet payload area. The packet memory pool is basically a series of packets—headers followed immediately by the packet payload. The packet header (***NX_PACKET***) and the layout of the packet pool are pictured in Figure 3.

For network devices driver that are able to perform zero copy operations, typically the starting address of the packet payload area is programmed into the DMA logic. Certain DMA engines have alignment requirement on the payload area.

*It is important for the network driver to use the ***nx_packet_transmit_release*** function when transmission of a packet is complete. This function checks to make sure the packet is not part of a TCP output queue before it is actually placed back in the available pool.*

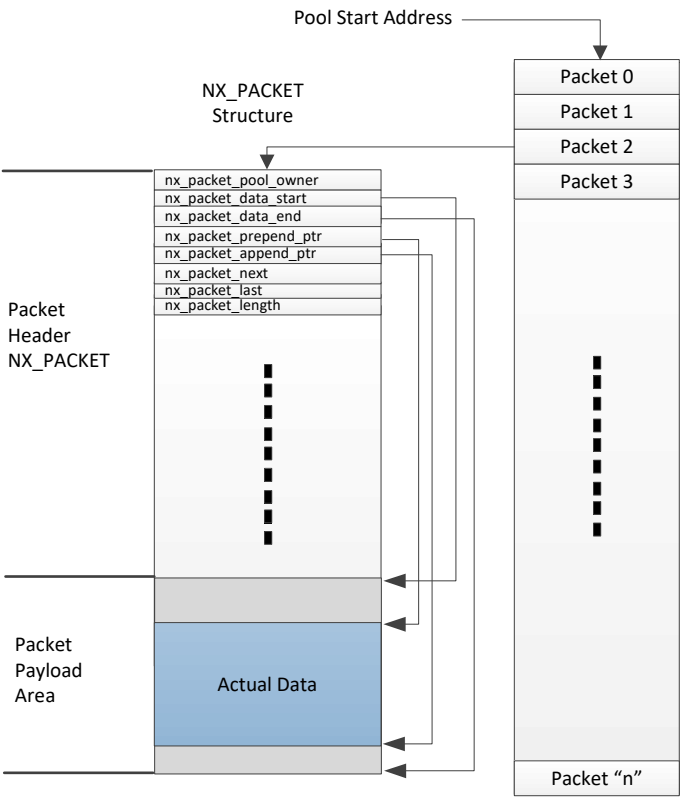

FIGURE 3. Packet Header and Packet Pool Layout

The fields of the packet header are defined as follows. Note that this table is not a comprehensive list of all the members in the *NX_PACKET* structure.

Packet header

nx_packet_pool_owner

Purpose

This field points to the packet pool that owns this particular packet. When the packet is released, it is released to this particular pool. With the pool ownership inside each packet, it is possible for a datagram to span multiple packets from multiple packet pools.

nx_packet_next

This field points to the next packet within the same frame. If NULL, there are no additional packets that are part of the frame.

nx_packet_last

This field points to the last packet within the same network packet. If NULL, this packet represents the entire network packet.

nx_packet_length

This field contains the total number of bytes in the entire network packet, including the total of all bytes in all packets chained together by the *nx_packet_next* member.

nx_packet_ip_interface

This field is the interface control block which is assigned to the packet when it is received by the interface driver, and by NetX for outgoing packets. An interface control block describes the interface e.g. network address, MAC address, IP address and interface status such as link enabled and physical mapping required.

nx_packet_data_start

This field points to the start of the physical payload area of this packet. It does not have to be immediately following the *NX_PACKET* header, but that is the default for the ***nx_packet_pool_create*** service.

nx_packet_data_end

This field points to the end of the physical payload area of this packet. The difference between this field and the *nx_packet_data_start* field represents the payload size.

Packet header***nx_packet_prepend_ptr*****Purpose**

This field points to the location of where packet data, either protocol header or actual data, is added in front of the existing packet data (if any) in the packet payload area. It must be greater than or equal to the *nx_packet_data_start* pointer location and less than or equal to the *nx_packet_append_ptr* pointer.

For performance reasons, NetX assumes that when the packet is passed into NetX services for transmission, the prepend pointer points to long word aligned address.

nx_packet_append_ptr

This field points to the end of the data currently in the packet payload area. It must be in between the memory location pointed to by *nx_packet_prepend_ptr* and *nx_packet_data_end*. The difference between this field and the *nx_packet_prepend_ptr* field represents the amount of data in this packet.

nx_packet_fragment_next

This field is used to hold fragmented packets until the entire packet can be re-assembled.

nx_packet_pad

This field defines the length of padding in 4-byte words to achieve the desired alignment requirement. This field is removed if ***NX_PACKET_HEADER_PAD*** is not defined.

Packet Header Offsets

Packet header size is defined to allow enough room to accommodate the size of the header. The ***nx_packet_allocate*** service is used to allocate a packet and adjusts the prepend pointer in the packet according to the type of packet specified. The packet type tells NetX the offset required for inserting the protocol header (such as UDP, TCP, or ICMP) in front of the protocol data.

The following types are defined in NetX to take into account the IP header and physical layer (Ethernet)

header in the packet. In the latter case, it is assumed to be 16 bytes taking the required 4-byte alignment into consideration. IP packets are still defined in NetX for applications to allocate packets for IP networks. The following table shows symbols defined:

Packet Type	Value
NX_IP_PACKET	0x24
NX_UDP_PACKET	0x2c
NX_TCP_PACKET	0x38

Pool Capacity

The number of packets in a packet pool is a function of the payload size and the total number of bytes in the memory area supplied to the packet pool create service. The capacity of the pool is calculated by dividing the packet size (including the size of the NX_PACKET header, the payload size, and proper alignment) into the total number of bytes in the supplied memory area.

Thread Suspension

Application threads can suspend while waiting for a packet from an empty pool. When a packet is returned to the pool, the suspended thread is given this packet and resumed.

If multiple threads are suspended on the same packet pool, they are resumed in the order they were suspended (FIFO).

Pool Statistics and Errors

If enabled, the NetX packet management software keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for packet pools:

Total Packets in Pool
Free Packets in Pool
Pool Empty Allocation Requests
Pool Empty Allocation Suspensions
Invalid Packet Releases

All of these statistics and error reports, except for total and free packet count in pool, are built into NetX library unless ***NX_DISABLE_PACKET_INFO*** is defined. This data is available to the application with the ***nx_packet_pool_info_get*** service.

Packet Pool Control Block ***NX_PACKET_POOL***

The characteristics of each packet memory pool are found in its control block. It contains useful information such as the linked list of free packets, the number of free packets, and the payload size for packets in this pool. This structure is defined in the *nx_api.h* file.

Packet pool control blocks can be located anywhere in memory, but it is most common to make the control block a global structure by defining it outside the scope of any function.

IP Protocol

The Internet Protocol (IP) component of NetX is responsible for sending and receiving IP packets on the Internet. In NetX, it is the component ultimately responsible for sending and receiving TCP, UDP, ICMP, and IGMP messages, utilizing the underlying network driver.

NetX supports IP protocol (RFC 791)

IP Addresses

Each host on the Internet has a unique 32-bit identifier called an IP address. There are five classes of IP addresses as described in Figure 4. The ranges of the five IP address classes are as follows:

Class	Range
A	0.0.0.0 to 127.255.255.255
B	128.0.0.0 to 191.255.255.255
C	192.0.0.0 to 223.255.255.255
D	224.0.0.0 to 239.255.255.255
E	240.0.0.0 to 247.255.255.255

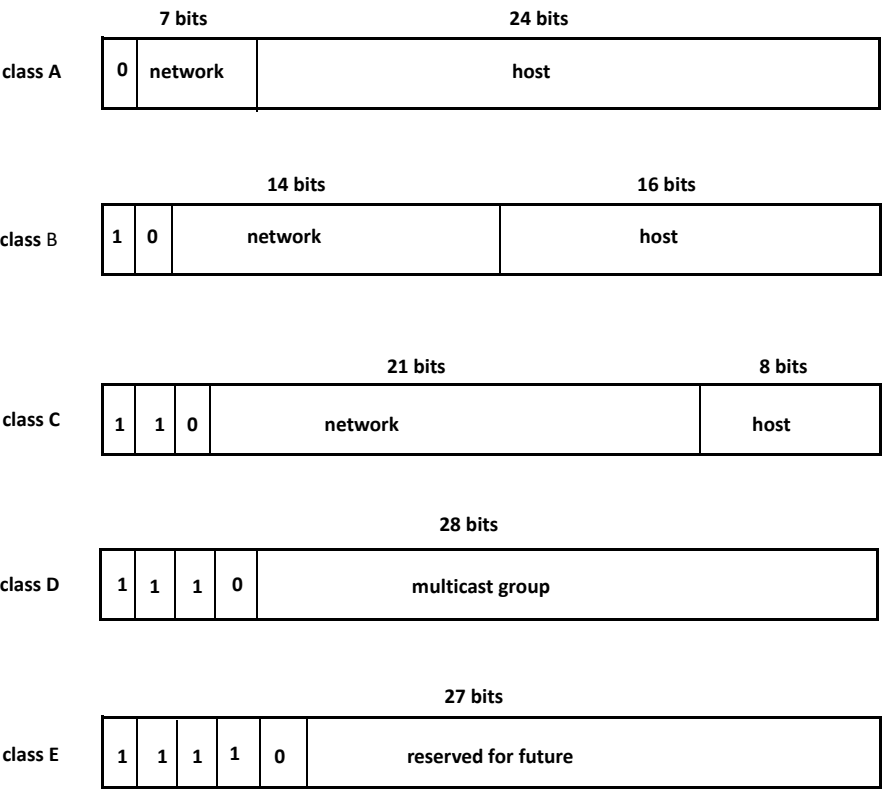

FIGURE 4. IP Address Structure

There are also three types of address specifications: *unicast*, *broadcast*, and *multicast*. Unicast addresses are those IP addresses that identify a specific host on the Internet. Unicast addresses can be either a source or a destination IP address. A broadcast address identifies all hosts on a specific network or sub-network and can only be used as destination addresses. Broadcast addresses are specified by having the host ID portion of the address set to ones. Multicast addresses (Class D) specify a dynamic group of hosts on the Internet. Members of the multicast group may join and leave whenever they wish.

i Only connectionless protocols like UDP over IP can utilize broadcast and the limited broadcast capability of the multicast group.

i The macro `IP_ADDRESS` is defined in `nx_api.h`. It allows easy specification of IP addresses using commas instead of a periods. For example, `IP_ADDRESS(128,0,0,0)` specifies the first class B address shown in Figure 4.

IP Gateway Address

Network gateways assist hosts on their networks to relay packets destined to destinations outside the local domain. Each node has some knowledge of which next hop to send to, either the destination one of its neighbors, or through a pre-programmed static routing table. However if these approaches fail, the node should forward the packet to its default gateway which has better knowledge on how to route the packet to its destination. Note that the default gateway must be directly accessible through one of the physical interfaces attached to the IP instance. The application calls `nx_ip_gateway_address_set` to configure IP default gateway address.

IP Header

For any IP packet to be sent on the Internet, it must have an IP header. When higher-level protocols (UDP, TCP, ICMP, or IGMP) call the IP component to send a packet, the IP transmit module places an IP header in front of the data. Conversely, when IP packets are received from the network, the IP component removes the IP header from the packet before delivery to the higher-level protocols. Figure 5 shows the format of the IP header.

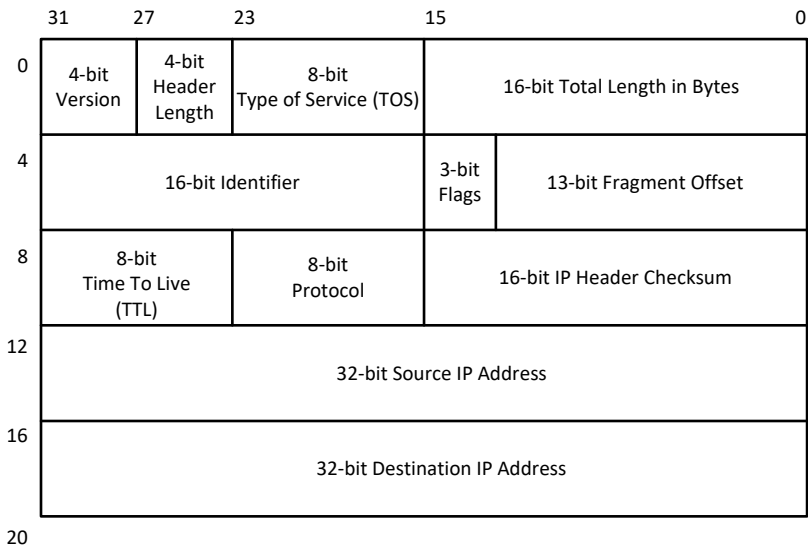

FIGURE 5. IP Header Format

All headers in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address. For example, the 4-bit version and the 4-bit header length of the IP header must be located on the first byte of the header.

The fields of the IP header are defined as follows:

IP Header Field	Purpose												
4-bit version	This field contains the version of IP this header represents. For IP version 4, which is what NetX supports, the value of this field is 4.												
4-bit header length	This field specifies the number of 32-bit words in the IP header. If no option words are present, the value for this field is 5.												
8-bit type of service (TOS)	This field specifies the type of service requested for this IP packet. Valid requests are as follows: <table><tr><th>TOS Request</th><th>Value</th></tr><tr><td>Normal</td><td>0x00</td></tr><tr><td>Minimum Delay</td><td>0x10</td></tr><tr><td>Maximum Data</td><td>0x08</td></tr><tr><td>Maximum Reliability</td><td>0x04</td></tr><tr><td>Minimum Cost</td><td>0x02</td></tr></table>	TOS Request	Value	Normal	0x00	Minimum Delay	0x10	Maximum Data	0x08	Maximum Reliability	0x04	Minimum Cost	0x02
TOS Request	Value												
Normal	0x00												
Minimum Delay	0x10												
Maximum Data	0x08												
Maximum Reliability	0x04												
Minimum Cost	0x02												
16-bit total length	This field contains the total length of the IP datagram in bytes, including the IP header. An IP datagram is the basic unit of information found on a TCP/IP Internet. It contains a destination and source address in addition to data. Because it is a 16-bit field, the maximum size of an IP datagram is 65,535 bytes.												
16-bit identification	The field is a number used to uniquely identify each IP datagram sent from a host. This number is typically incremented after an IP datagram is sent. It is especially useful in assembling received IP packet fragments.												
3-bit flags	This field contains IP fragmentation information. Bit 14 is the “don’t fragment” bit. If this bit is set, the outgoing IP datagram will not be fragmented. Bit 13 is the “more fragments” bit. If this bit is set, there are more fragments. If this bit is clear, this is the last fragment of the IP packet.												

IP Header Field

13-bit fragment offset

Purpose

This field contains the upper 13-bits of the fragment offset. Because of this, fragment offsets are only allowed on 8-byte boundaries. The first fragment of a fragmented IP datagram will have the “more fragments” bit set and have an offset of 0.

8-bit time to live (TTL)

This field contains the number of routers this datagram can pass, which basically limits the lifetime of the datagram.

8-bit protocol

This field specifies which protocol is using the IP datagram. The following is a list of valid protocols and their values:

Protocol	Value
ICMP	0x01
IGMP	0x02
TCP	0X06
UDP	0X11

16-bit checksum

This field contains the 16-bit checksum that covers the IP header only. There are additional checksums in the higher level protocols that cover the IP payload.

32-bit source IP address

This field contains the IP address of the sender and is always a host address.

32-bit destination IP address

This field contains the IP address of the receiver or receivers if the address is a broadcast or multicast address.

Creating IP Instances

IP instances are created either during initialization or during runtime by application threads. The initial IP address, network mask, default packet pool, media driver, and memory and priority of the internal IP thread are defined by the ***`nx_ip_create`*** service. If the application initializes the IP instance with its IP address set to an invalid address(0.0.0.0), it is assumed that the interface address is going to

resolved by manual configuration later, via RARP, or through DHCP or similar protocols.

For systems with multiple network interfaces, the primary interface is designated when calling ***nx_ip_create***. Each additional interface can be attached to the same IP instance by calling ***nx_ip_interface_attach***. This service stores information about the network interface (such as IP address, network mask) in the interface control block, and associates the driver instance with the interface control block in the IP instance. As the driver receives a data packet, it needs to store the interface information in the NX_PACKET structure before forwarding it to the IP receive logic. Note an IP instance must already be created before attaching any interfaces.

IP Send

The IP send processing in NetX is very streamlined. The prepend pointer in the packet is moved backwards to accommodate the IP header. The IP header is completed (with all the options specified by the calling protocol layer), the IP checksum is computed in-line, and the packet is dispatched to the associated network driver. In addition, outgoing fragmentation is also coordinated from within the IP send processing.

For IP, NetX initiates ARP requests if physical mapping is needed for the destination IP address.

i

*For IP connectivity, packets that require IP address resolution (i.e., physical mapping) are queued on the ARP queue until the number of packets queued exceeds the ARP queue depth (defined by the symbol **NX_ARP_MAX_QUEUE_DEPTH**). If the queue depth is reached, NetX will remove the oldest packet on the queue and continue waiting for address resolution for the remaining packets enqueued. On*

the other hand, if an ARP entry is not resolved, the pending packets on the ARP entry are released upon ARP entry timeout.

For systems with multiple network interfaces, NetX chooses an interface based on the destination IP address. The following procedure applies to the selection process:

1. If a destination address is IP broadcast or multi-cast, and if a valid outgoing interface is specified, use that interface. Otherwise, the first physical interface is used.
2. If the destination address is found in the static routing table, the interface associated with the gateway is used.
3. If the destination is on-link, the on-link interface is used.
4. If the destination address is a loopback address 127.0.0.1, the loopback interface is used.
5. If the default gateway is properly configured, use the interface associated with the default gateway to transmit the packet.
6. The output packet is dropped if all the above fails.

IP Receive

The IP receive processing is either called from the network driver or the internal IP thread (for processing packets on the deferred received packet queue). The IP receive processing examines the protocol field and attempts to dispatch the packet to the proper protocol component. Before the packet is actually dispatched, the IP header is removed by advancing the prepend pointer past the IP header.

IP receive processing also detects fragmented IP packets and performs the necessary steps to re-assemble them if fragmentation is enabled. If fragmentation is needed but not enabled, the packet is dropped.

NetX determines the appropriate network interface based on the interface specified in the packet. If the packet interface is NULL, NetX defaults to the primary interface. This is done to guarantee compatibility with legacy NetX Ethernet drivers.

Raw IP Send

A raw IP packet is an IP frame that contains upper layer protocol payload not directly supported (and processed) by NetX. A raw packet allows developers to define their own IP-based applications. An application may send raw IP packets directly using the ***nx_ip_raw_packet_send*** service if raw IP packet processing has been enabled with the ***nx_ip_raw_packet_enabled*** service. If the destination address is a multicast or broadcast address, however, NetX will default to the first (primary) interface. Therefore, to send such packets out on secondary interfaces, the application must use the ***nx_ip_raw_packet_interface_send*** service to specify the source address to use for the outgoing packet.

Raw IP Receive

If raw IP packet processing is enabled, the application may receive raw IP packets through the ***nx_ip_raw_packet_receive*** service. All incoming packets are processed according to the protocol specified in the IP header. If the protocol specifies UDP, TCP, IGMP or ICMP, NetX will process the packet using the appropriate handler for the packet protocol type. If the protocol is not one of these protocols, and raw IP receive is enabled, the incoming packet will be put into the raw packet queue waiting for the application to receive it via the ***nx_ip_raw_packet_receive*** service. In addition, application threads may suspend with an optional timeout while waiting for a raw IP packet.

Default Packet Pool

Each IP instance is given a default packet pool during creation. This packet pool is used to allocate packets for ARP, RARP, ICMP, IGMP, various TCP control packets (such as SYN, ACK). If the default packet pool is empty when NetX needs to allocate a packet, NetX may have to abort the particular operation, and will return an error message if possible.

IP Helper Thread

Each IP instance has a helper thread. This thread is responsible for handling all deferred packet processing and all periodic processing. The IP helper thread is created in ***nx_ip_create***. This is where the thread is given its stack and priority. Note that the first processing in the IP helper thread is to finish the network driver initialization associated with the IP create service. After the network driver initialization is complete, the helper thread starts an endless loop to process packet and periodic requests.

i

If unexplained behavior is seen within the IP helper thread, increasing its stack size during the IP create service is the first debugging step. If the stack is too small, the IP helper thread could possibly be overwriting memory, which may cause unusual problems.

Thread Suspension

Application threads can suspend while attempting to receive raw IP packets. After a raw packet is received, the new packet is given to the first thread suspended and that thread is resumed. NetX services for receiving packets all have an optional suspension timeout. When a packet is received or the timeout expires, the application thread is resumed with the appropriate completion status.

IP Statistics and Errors

If enabled, the NetX keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP instance:

- Total IP Packets Sent
- Total IP Bytes Sent
- Total IP Packets Received
- Total IP Bytes Received
- Total IP Invalid Packets
- Total IP Receive Packets Dropped
- Total IP Receive Checksum Errors
- Total IP Send Packets Dropped
- Total IP Fragments Sent
- Total IP Fragments Received

All of these statistics and error reports are available to the application with the ***nx_ip_info_get*** service.

IP Control Block NX_IP

The characteristics of each IP instance are found in its control block. It contains useful information such as the IP addresses and network masks of each network device, and a table of neighbor IP and physical hardware address mapping. This structure is defined in the ***nx_api.h*** file.

IP instance control blocks can be located anywhere in memory, but it is most common to make the control block a global structure by defining it outside the scope of any function.

Static IP Routing

The static routing feature allows an application to specify an IP network and next hop address for specific out of network destination IP addresses. If static routing is enabled, NetX searches through the static routing table for an entry matching the destination address of the packet to send. If no match is found, NetX searches through the list of physical interfaces and chooses a source IP address and

next hop address based on the destination IP address and the network mask. If the destination does not match any of the IP addresses of the network drivers attached to the IP instance, NetX chooses an interface that is directly connected to the default gateway, and uses the IP address of the interface as source address, and the default gateway as the next hop.

Entries can be added and removed from the static routing table using the ***nx_ip_static_route_add*** and ***nx_ip_static_route_delete*** services, respectively. To use static routing, the host application must enable this feature by defining ***NX_ENABLE_IP_STATIC_ROUTING***.

When adding an entry to the static routing table, NetX checks for a matching entry for the specified destination address already in the table. If one exists, it gives preference to the entry with the smaller network (longer prefix) in the network mask.

IP Fragmentation

The network device may have limits on the size of outgoing packets. This limit is called the maximum transmission unit (MTU). IP MTU is the largest IP frame size a link layer driver is able to transmit without fragmenting the IP packet. During a device driver initialization phase, the driver module must configure its IP MTU size via the service ***nx_ip_interface_mtu_set***.

Although not recommended, the application may generate datagrams larger than the underlying IP MTU supported by the device. Before transmitting such IP datagram, the IP layer must fragment these packets. On receiving fragmented IP frames, the receiving end must store all fragmented IP frames with the same fragmentation ID, and reassemble them in order. If the IP receive logic is unable to

collect all the fragments to restore the original IP frame in time, all the fragments are released. It is up to the upper layer protocol to detect such packet loss and recover from it.

In order to support IP fragmentation and reassembly operation, the system designer must enable the IP fragmentation feature in NetX using the ***nx_ip_fragment_enable*** service. If this feature is not enabled, incoming fragmented IP packets are discarded, as well as packets that exceed the network driver's MTU.

*The IP Fragmentation logic can be removed completely by defining ***NX_DISABLE_FRAGMENTATION*** when building the NetX library. Doing so helps reduce the code size of NetX.*

Address Resolution Protocol (ARP) in IP

The Address Resolution Protocol (ARP) is responsible for dynamically mapping 32-bit IP addresses to those of the underlying physical media (RFC 826). Ethernet is the most typical physical media, and it supports 48-bit addresses. The need for ARP is determined by the network driver supplied to the ***nx_ip_create*** service. If physical mapping is required, the network driver must set the flag ***nx_interface_address_mapping_needed*** in the interface structure.

ARP Enable

For ARP to function properly, it must first be enabled by the application with the ***nx_arp_enable*** service. This service sets up various data structures for ARP processing, including the creation of an ARP cache

area from the memory supplied to the ARP enable service.

ARP Cache

The ARP cache can be viewed as an array of internal ARP mapping data structures. Each internal structure is capable of maintaining the relationship between an IP address and a physical hardware address. In addition, each data structure has link pointers so it can be part of multiple linked lists.

Application can look up an IP address from the ARP cache by supplying hardware MAC address using the service ***nx_arp_ip_address_find*** if the mapping exists in the ARP table. Similarly, the service ***nx_arp_hardware_address_find*** returns the MAC address for a given IP address.

ARP Dynamic Entries

By default, the ARP enable service places all entries in the ARP cache on the list of available dynamic ARP entries. A dynamic ARP entry is allocated from this list by NetX when a send request to an unmapped IP address is detected. After allocation, the ARP entry is set up and an ARP request is sent to the physical media.

A dynamic entry can also be created by the service ***nx_arp_dynamic_entry_set***.

If all dynamic ARP entries are in use, the least recently used ARP entry is replaced with a new mapping.

ARP Static Entries

The application can also set up static ARP mapping by using the ***nx_arp_static_entry_create*** service. This service allocates an ARP entry from the dynamic ARP entry list and places it on the static list

with the mapping information supplied by the application. Static ARP entries are not subject to reuse or aging. The application can delete a static entry by using the service ***nx_arp_static_entry_delete***. To remove all static entries in the ARP table, the application may use the service ***nx_arp_static_entries_delete***.

Automatic ARP Entry

NetX records the peer's IP/MAC mapping after the peer responds to the ARP request. NetX also implements the automatic ARP entry feature where it records peer IP/MAC address mapping based on unsolicited ARP requests from the network. This feature allows the ARP table to be populated with peer information, reducing the delay needed to go through the ARP request/response cycle. However the downside with enabling automatic ARP is that the ARP table tend to fill up quickly on a busy network with many nodes on the local link, which would eventually lead to ARP entry replacement.

This feature is enabled by default. To disable it, the NetX library must be compiled with the symbol ***NX_DISABLE_ARP_AUTO_ENTRY*** defined.

ARP Messages

As mentioned previously, an ARP request message is sent when the IP task detects that mapping is needed for an IP address. ARP requests are sent periodically (every ***NX_ARP_UPDATE_RATE*** seconds) until a corresponding ARP response is received. A total of ***NX_ARP_MAXIMUM_RETRIES*** ARP requests are made before the ARP attempt is abandoned. When an ARP response is received, the associated physical address information is stored in the ARP entry that is in the cache.

For multihome systems, NetX determines which interface to send the ARP requests and responses based on destination address specified.

i

*Outgoing IP packets are queued while NetX waits for the ARP response. The number of outgoing IP packets queued is defined by the constant **`NX_ARP_MAX_QUEUE_DEPTH`**.*

NetX also responds to ARP requests from other nodes on the local IP network. When an external ARP request is made that matches the current IP address of the interface that receives the ARP request, NetX builds an ARP response message that contains the current physical address.

The formats of Ethernet ARP requests and responses are shown in Figure 6 and are described below:

Request/Response Field	Purpose
<i>Ethernet Destination Address</i>	This 6-byte field contains the destination address for the ARP response and is a broadcast (all ones) for ARP requests. This field is setup by the network driver.
<i>Ethernet Source Address</i>	This 6-byte field contains the address of the sender of the ARP request or response and is set up by the network driver.
<i>Frame Type</i>	This 2-byte field contains the type of Ethernet frame present and, for ARP requests and responses, this is equal to 0x0806. This is the last field the network driver is responsible for setting up.
<i>Hardware Type</i>	This 2-byte field contains the hardware type, which is 0x0001 for Ethernet.
<i>Protocol Type</i>	This 2-byte field contains the protocol type, which is 0x0800 for IP addresses.
<i>Hardware Size</i>	This 1-byte field contains the hardware address size, which is 6 for Ethernet addresses.

Offset				
0	Ethernet Destination Address (6-bytes)			
6	Ethernet Source Address (6-bytes)			
12	Frame Type 0x0806		Hardware Type 0x0001	Protocol Type 0x0800
18	H Size 6	P Size 4	Operation (2-bytes)	
22	Sender's Ethernet Address (6-bytes)			
28	Sender's IP Address (4-bytes)			
32	Target's Ethernet Address (6-bytes)			
38	Target's IP Address (4-bytes)			

FIGURE 6. ARP Packet Format

Request/Response Field	Purpose
Protocol Size	This 1-byte field contains the IP address size, which is 4 for IP addresses.
Operation Code	This 2-byte field contains the operation for this ARP packet. An ARP request is specified with the value of 0x0001, while an ARP response is represented by a value of 0x0002.
Sender Ethernet Address	This 6-byte field contains the sender's Ethernet address.
Sender IP Address	This 4-byte field contains the sender's IP address.
Target Ethernet Address	This 6-byte field contains the target's Ethernet address.
Target IP Address	This 4-byte field contains the target's IP address.

ARP requests and responses are Ethernet-level packets. All other TCP/IP packets are encapsulated by an IP packet header.

*All ARP messages in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.*

ARP Aging

NetX supports automatic dynamic ARP entry invalidation. ***NX_ARP_EXPIRATION_RATE*** specifies the number of seconds an established IP address to physical mapping stays valid. After expiration, the ARP entry is removed from the ARP cache. The next attempt to send to the corresponding IP address will result in a new ARP request. Setting ***NX_ARP_EXPIRATION_RATE*** to zero disables ARP aging, which is the default configuration.

ARP Defend

When an ARP request or ARP response packet is received and the sender has the same IP address, which conflicts with the IP address of this node, NetX sends an ARP request for that address as a defense. If the conflict ARP packet is received more than once in 10 seconds, NetX does not send more defend packets. The default interval 10 seconds can be redefined by ***NX_ARP_DEFEND_INTERVAL***. This behavior follows the policy specified in 2.4(c) of RFC5227. Since Windows XP ignores ARP announcement as a response for its ARP probe, user can define ***NX_ARP_DEFEND_BY_REPLY*** to send ARP response as additional defence.

ARP Statistics and Errors

If enabled, the NetX ARP software keeps track of several statistics and errors that may be useful to the

application. The following statistics and error reports are maintained for each IP's ARP processing:

- Total ARP Requests Sent
- Total ARP Requests Received
- Total ARP Responses Sent
- Total ARP Responses Received
- Total ARP Dynamic Entries
- Total ARP Static Entries
- Total ARP Aged Entries
- Total ARP Invalid Messages

All these statistics and error reports are available to the application with the ***nx_arp_info_get*** service.

Reverse Address Resolution Protocol (RARP) in IP

The Reverse Address Resolution Protocol (RARP) is the protocol for requesting network assignment of the host's 32-bit IP addresses (RFC 903). This is done through an RARP request and continues periodically until a network member assigns an IP address to the host network interface in an RARP response. The application creates an IP instance by the service ***nx_ip_create*** with a zero IP address. If RARP is enabled by the application, it can use the RARP protocol to request an IP address from the network server accessible through the interface that has a zero IP address.

RARP Enable

To use RARP, the application must create the IP instance with an IP address of zero, then enable RARP using the service ***nx_rarp_enable***. For multihomed systems, at least one network device associated with the IP instance must have an IP address of zero. The RARP processing periodically

sends RARP request messages for the NetX system requiring an IP address until a valid RARP reply with the network designated IP address is received. At this point, RARP processing is complete.

After RARP has been enabled, it is disabled automatically after all interface addresses are resolved. The application may force RARP to terminate by using the service ***nx_rarp_disable***.

RARP Request

The format of an RARP request packet is almost identical to the ARP packet shown in Figure 6 on page 73. The only difference is the frame type field is 0x8035 and the *Operation Code* field is 3, designating an RARP request. As mentioned previously, RARP requests will be sent periodically (every ***NX_RARP_UPDATE_RATE*** seconds) until a RARP reply with the network assigned IP address is received.

*All RARP messages in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.*

RARP Reply

RARP reply messages are received from the network and contain the network assigned IP address for this host. The format of an RARP reply packet is almost identical to the ARP packet shown in Figure 6. The only difference is the frame type field is 0x8035 and the *Operation Code* field is 4, which designates an RARP reply. After received, the IP address is setup in the IP instance, the periodic RARP request is disabled, and the IP instance is now ready for normal network operation.

For multihome hosts, the IP address is applied to the requesting network interface. If there are other

network interfaces still requesting an IP address assignment, the periodic RARP service continues until all interface IP address requests are resolved.

*The application should not use the IP instance until the RARP processing is complete. The **`nx_ip_status_check`** may be used by applications to wait for the RARP completion. For multihomed systems, the application should not use the requesting interface until the RARP processing is complete on that interface. Status of the IP address on the secondary device can be checked with the **`nx_ip_interface_status_check`** service.*

RARP Statistics and Errors

If enabled, the NetX RARP software keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP's RARP processing:

- Total RARP Requests Sent
- Total RARP Responses Received
- Total RARP Invalid Messages

All these statistics and error reports are available to the application with the **`nx_rarp_info_get`** service.

Internet Control Message Protocol (ICMP)

Internet Control Message Protocol for IP (ICMP) is limited to passing error and control information between IP network members.

Like most other application layer (e.g., TCP/IP) messages, ICMP messages are encapsulated by an IP header with the ICMP protocol designation.

ICMP Statistics and Errors

If enabled, NetX keeps track of several ICMP statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP's ICMP processing:

- Total ICMP Pings Sent
- Total ICMP Ping Timeouts
- Total ICMP Ping Threads Suspended
- Total ICMP Ping Responses Received
- Total ICMP Checksum Errors
- Total ICMP Unhandled Messages

All these statistics and error reports are available to the application with the ***nx_icmp_info_get*** service.

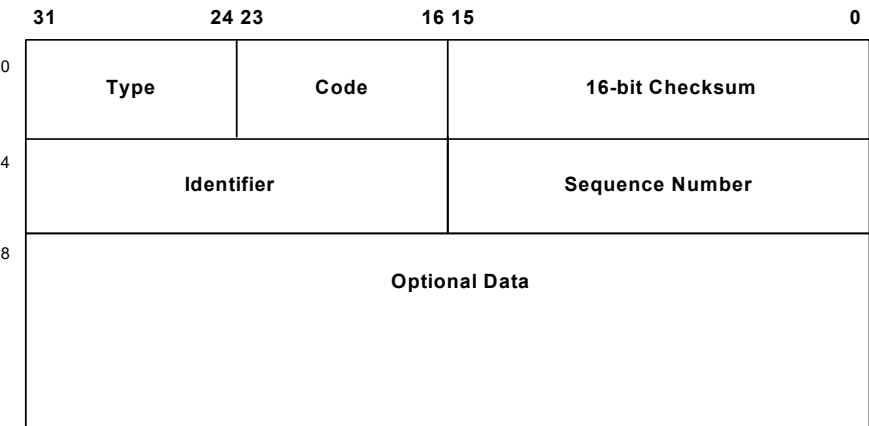

ICMP Enable

Before ICMP messages can be processed by NetX, the application must call the ***nx_icmp_enable*** service to enable ICMP processing. After this is done, the application can issue ping requests and field incoming ping packets.

ICMP Echo Request

An echo request is one type of ICMP message that is typically used to check for the existence of a specific node on the network, as identified by its host IP address. The popular ping command is implemented using ICMP echo request/echo reply messages. If the specific host is present, its network stack processes the

ping request and responses with a ping response. Figure 7 details the ICMP ping message format.

(Note: IP header is prepended)

FIGURE 7. ICMP Ping Message

All ICMP messages in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.

The following table describes the ICMP header format:

Header Field

Purpose

Type

This field specifies the ICMP message (bits 31-24). The most common are:

- 0 Echo Reply
- 8 Echo Request

Code

This field is context specific on the type field (bits 23-16). For an echo request or reply the code is set to zero.

Checksum

This field contains the 16-bit checksum of the one's complement sum of the ICMP message including the entire the ICMP header starting with the Type field. Before generating the checksum, the checksum field is cleared.

Identification

This field contains an ID value identifying the host; a host should use the ID extracted from an ECHO request in the ECHO REPLY (bits 31-16).

Sequence number

This field contains an ID value; a host should use the ID extracted from an ECHO request in the ECHO REPLY (bits 31-16). Unlike the identifier field, this value will change in a subsequent Echo request from the same host (bits 15-0).

ICMP Echo Response

A ping response is another type of ICMP message that is generated internally by the ICMP component in response to an external ping request. In addition to acknowledgement, the ping response also contains a copy of the user data supplied in the ping request.

Internet Group Management Protocol (IGMP)

The Internet Group Management Protocol (IGMP) provides a device to communicate with its neighbors and its routers that it intends to receive, or join, an IP multicast group (RFC 1112 and RFC 2236). A multicast group is basically a dynamic collection of network members and is represented by a Class D IP address. Members of the multicast group may leave at any time, and new members may join at any time. The coordination involved in joining and leaving the group is the responsibility of IGMP.

IGMP Enable

Before any multicasting activity can take place in NetX, the application must call the ***nx_igmp_enable*** service. This service performs basic IGMP initialization in preparation for multicast requests.

Multicast IP Addressing

As mentioned previously, multicast addresses are actually Class D IP addresses as shown in Figure 4 on page 58. The lower 28-bits of the Class D address correspond to the multicast group ID. There are a series of pre-defined multicast addresses; however, the *all hosts address* (244.0.0.1) is particularly important to IGMP processing. The *all hosts address* is used by routers to query all multicast members to report on which multicast groups they belong to.

Physical Address Mapping in IP

Class D multicast addresses map directly to physical Ethernet addresses ranging from 01.00.5e.00.00.00 through 01.00.5e.7f.ff.ff. The lower 23 bits of the IP multicast address map directly to the lower 23 bits of the Ethernet address.

Multicast Group Join

Applications that need to join a particular multicast group may do so by calling the ***nx_igmp_multicast_join*** service. This service keeps track of the number of requests to join this multicast group. If this is the first application request to join the multicast group, an IGMP report is sent out on the primary network indicating this host's intention to join the group. Next, the network driver is called to set up for listening for packets with the Ethernet address for this multicast group.

In a multihome system, if the multicast group is accessible via a specific interface, application shall use the service ***nx_igmp_multicast_interface_join***

instead of ***nx_igmp_multicast_join***, which is limited to multicast groups on the primary network.

Multicast Group Leave

Applications that need to leave a previously joined multicast group may do so by calling the ***nx_igmp_multicast_leave*** service. This service reduces the internal count associated with how many times the group was joined. If there are no outstanding join requests for a group, the network driver is called to disable listening for packets with this multicast group's Ethernet address.

Multicast Loopback

An application may wish to receive multicast traffic originated from one of the sources on the same node. This requires the IP multicast component to have loopback enabled by using the service ***nx_igmp_loopback_enable***.

IGMP Report Message

When the application joins a multicast group, an IGMP report message is sent via the network to indicate the host's intention to join a particular multicast group. The format of the IGMP report message is shown in Figure 8. The multicast group address is used for both the group message in the IGMP report message and the destination IP address.

In the figure above (Figure 8), the IGMP header contains a version/type field, maximum response time, a checksum field, and a multicast group address field. For IGMPv1 messages, the Maximum Response Time field is always set to zero, as this is not part of the IGMPv1 protocol. The Maximum Response Time field is set when the host receives a Query type IGMP message and cleared when a host

(Note: IP header is prepended)

FIGURE 8. IGMP Report Message

receives another host's Report type message as defined by the IGMPv2 protocol.

The following describes the IGMP header format:

Header Field	Purpose
Version	This field specifies the IGMP version (bits 31- 28).
Type	This field specifies the type of IGMP message (bits 27 -24).
Maximum Response Time	Not used in IGMPv1. In IGMPv2 this field serves as the maximum response time.
Checksum	This field contains the 16-bit checksum of the one's complement sum of the IGMP message starting with the IGMP version (bits 0-15)
Group Address	32-bit class D group IP address

IGMP report messages are also sent in response to IGMP query messages sent by a multicast router. Multicast routers periodically send query messages out to see which hosts still require group membership. Query messages have the same format as the IGMP Report message shown in Figure 8. The only differences are the IGMP type is equal to 1 and the group address field is set to 0. IGMP Query

messages are sent to the *all hosts* IP address by the multicast router. A host that still wishes to maintain group membership responds by sending another IGMP Report message.

*All messages in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.*

IGMP Statistics and Errors

If enabled, the NetX IGMP software keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP's IGMP processing:

- Total IGMP Reports Sent
- Total IGMP Queries Received
- Total IGMP Checksum Errors
- Total IGMP Current Groups Joined

All these statistics and error reports are available to the application with the ***nx_igmp_info_get*** service.

User Datagram Protocol (UDP)

The User Datagram Protocol (UDP) provides the simplest form of data transfer between network members (RFC 768). UDP data packets are sent from one network member to another in a best effort fashion; i.e., there is no built-in mechanism for acknowledgement by the packet recipient. In addition, sending a UDP packet does not require any connection to be established in advance. Because of this, UDP packet transmission is very efficient.

UDP Header

UDP places a simple packet header in front of the application’s data on transmission, and removes a similar UDP header from the packet on reception before delivering a received UDP packet to the application. UDP utilizes the IP protocol for sending and receiving packets, which means there is an IP header in front of the UDP header when the packet is on the network. Figure 9 shows the format of the UDP header.

(Note: IP header is prepended)

FIGURE 9. UDP Header

*All headers in the UDP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.*

The following describes the UDP header format:

Header Field	Purpose
16-bit source port number	This field contains the port on which the UDP packet is being sent from. Valid UDP ports range from 1 through 0xFFFF.
16-bit destination port number	This field contains the UDP port to which the packet is being sent to. Valid UDP ports range from 1 through 0xFFFF.

Header Field	Purpose
16-bit UDP length	This field contains the number of bytes in the UDP packet, including the size of the UDP header.
16-bit UDP checksum	This field contains the 16-bit checksum for the packet, including the UDP header, the packet data area, and the pseudo IP header.

UDP Enable Before UDP packet transmission is possible, the application must first enable UDP by calling the ***nx_udp_enable*** service. After enabled, the application is free to send and receive UDP packets.

UDP Socket Create UDP sockets are created either during initialization or during runtime by application threads. The initial type of service, time to live, and receive queue depth are defined by the ***nx_udp_socket_create*** service. There are no limits on the number of UDP sockets in an application.

UDP Checksum UDP specifies a one's complement 16-bit checksum that covers the IP pseudo header (consisting of the source IP address, destination IP address, and the protocol/length IP word), the UDP header, and the UDP packet data. If the calculated UDP checksum is 0, it is stored as all ones (0xFFFF). If the sending socket has the UDP checksum logic disabled, a zero is placed in the UDP checksum field to indicate the checksum was not calculated.

If the UDP checksum does not match the computed checksum by the receiver, the UDP packet is simply discarded.

On the IP network, UDP checksum is optional. NetX allows an application to enable or disable UDP checksum calculation on a per-socket basis. By default, the UDP socket checksum logic is enabled. The application can disable checksum logic for a particular UDP socket by calling the ***nx_udp_socket_checksum_disable*** service.

Certain Ethernet controllers are able to generate the UDP checksum on the fly. If the system is able to use hardware checksum computation feature, the NetX library can be built without the checksum logic. To disable UDP software checksum, the NetX library must be built with the following symbols defined: ***NX_DISABLE_UDP_TX_CHECKSUM*** and ***NX_DISABLE_UDP_RX_CHECKSUM*** (described in Chapter two). The configuration options remove UDP checksum logic from NetX entirely, while calling the ***nx_udp_socket_checksum_disable*** service allows the application to disable IP UDP checksum processing on a per socket basis.

UDP Ports and Binding

A UDP port is a logical end point in the UDP protocol. There are 65,535 valid ports in the UDP component of NetX, ranging from 1 through 0xFFFF. To send or receive UDP data, the application must first create a UDP socket, then bind it to a desired port. After binding a UDP socket to a port, the application may send and receive data on that socket.

UDP Fast Path™

The UDP Fast Path™ is the name for a low packet overhead path through the NetX UDP implementation. Sending a UDP packet requires just a few function calls: ***nx_udp_socket_send***, ***nx_ip_packet_send***, and the eventual call to the network driver. ***nx_udp_socket_send*** is available in NetX for existing NetX applications and is only applicable for IP packets. The preferred method, however, is to use ***nx_udp_socket_send*** service

discussed below. On UDP packet reception, the UDP packet is either placed on the appropriate UDP socket receive queue or delivered to a suspended application thread in a single function call from the network driver's receive interrupt processing. This highly optimized logic for sending and receiving UDP packets is the essence of UDP Fast Path technology.

UDP Packet Send

Sending UDP data over IP networks is easily accomplished by calling the ***nx_udp_socket_send*** function. The caller must set the IP version in the *IP address* field. NetX will determine the best source address for transmitted UDP packets based on the destination IP address. This service places a UDP header in front of the packet data and sends it out onto the network using an internal IP send routine. There is no thread suspension on sending UDP packets because all UDP packet transmissions are processed immediately.

For multicast or broadcast destinations, the application should specify the source IP address to use if the NetX device has multiple IP addresses to choose from. This can be done with the services ***nx_udp_socket_interface_send***.

*If ***nx_udp_socket_send*** is used for transmitting multicast or broadcast packets, the IP address of the first interface is used as source address.*

If UDP checksum logic is enabled for this socket, the checksum operation is performed in the context of the calling thread, without blocking access to the UDP or IP data structures.

*The UDP payload data residing in the ***NX_PACKET*** structure should reside on a long-word boundary. The application needs to leave sufficient space between the prepend pointer and the data start*

pointer for NetX to place the UDP, IP, and physical media headers.

UDP Packet Receive

Application threads may receive UDP packets from a particular socket by calling ***nx_udp_socket_receive***. The socket receive function delivers the oldest packet on the socket's receive queue. If there are no packets on the receive queue, the calling thread can suspend (with an optional timeout) until a packet arrives.

The UDP receive packet processing (usually called from the network driver's receive interrupt handler) is responsible for either placing the packet on the UDP socket's receive queue or delivering it to the first suspended thread waiting for a packet. If the packet is queued, the receive processing also checks the maximum receive queue depth associated with the socket. If this newly queued packet exceeds the queue depth, the oldest packet in the queue is discarded.

UDP Receive Notify

If the application thread needs to process received data from more than one socket, the ***nx_udp_socket_receive_notify*** function should be used. This function registers a receive packet callback function for the socket. Whenever a packet is received on the socket, the callback function is executed.

The contents of the callback function is application-specific; however, it would most likely contain logic to inform the processing thread that a packet is now available on the corresponding socket.

Peer Address and Port

On receiving a UDP packet, application may find the sender's IP address and port number by using the service ***nx_udp_packet_info_extract***. On

successful return, this service provides information on the sender's IP address, sender's port number, and the local interface through which the packet was received.

Thread Suspension

As mentioned previously, application threads can suspend while attempting to receive a UDP packet on a particular UDP port. After a packet is received on that port, it is given to the first thread suspended and that thread is then resumed. An optional timeout is available when suspending on a UDP receive packet, a feature available for most NetX services.

UDP Socket Statistics and Errors

If enabled, the NetX UDP socket software keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP/UDP instance:

- Total UDP Packets Sent
- Total UDP Bytes Sent
- Total UDP Packets Received
- Total UDP Bytes Received
- Total UDP Invalid Packets
- Total UDP Receive Packets Dropped
- Total UDP Receive Checksum Errors
- UDP Socket Packets Sent
- UDP Socket Bytes Sent
- UDP Socket Packets Received
- UDP Socket Bytes Received
- UDP Socket Packets Queued
- UDP Socket Receive Packets Dropped
- UDP Socket Checksum Errors

All these statistics and error reports are available to the application with the ***`nx_udp_info_get`*** service for UDP statistics amassed over all UDP sockets, and the ***`nx_udp_socket_info_get`*** service for UDP statistics on the specified UDP socket.

UDP Socket Control Block NX_UDP_SOCKET

The characteristics of each UDP socket are found in the associated NX_UDP_SOCKET control block. It contains useful information such as the link to the IP data structure, the network interface for the sending and receiving paths, the bound port, and the receive packet queue. This structure is defined in the *nx_api.h* file.

Transmission Control Protocol (TCP)

The Transmission Control Protocol (TCP) provides reliable stream data transfer between two network members (RFC 793). All data sent from one network member are verified and acknowledged by the receiving member. In addition, the two members must have established a connection prior to any data transfer. All this results in reliable data transfer; however, it does require substantially more overhead than the previously described UDP data transfer.

TCP Header

On transmission, TCP header is placed in front of the data from the user. On reception, TCP header is removed from the incoming packet, leaving only the user data available to the application. TCP utilizes the IP protocol to send and receive packets, which means there is an IP header in front of the TCP header when the packet is on the network. Figure 10 shows the format of the TCP header.

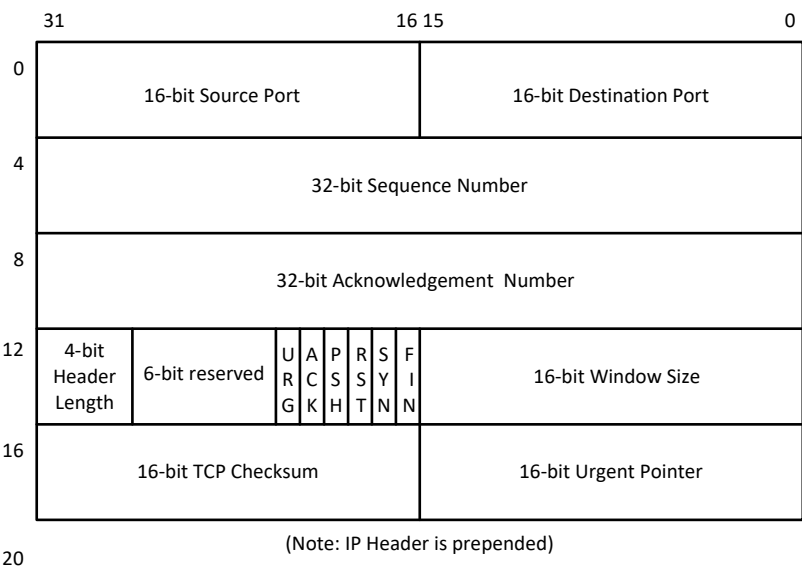

FIGURE 10. TCP Header

The following describes the TCP header format:

Header Field	Purpose
16-bit source port number	This field contains the port the TCP packet is being sent out on. Valid TCP ports range from 1 through 0xFFFF.
16-bit destination port number	This field contains the TCP port the packet is being sent to. Valid TCP ports range from 1 through 0xFFFF.
32-bit sequence number	This field contains the sequence number for data sent from this end of the connection. The original sequence is established during the initial connection sequence between two TCP nodes. Every data transfer from that point results in an increment of the sequence number by the amount bytes sent.

Header Field**Purpose****32-bit
acknowledgement
number**

This field contains the sequence number corresponding to the last byte received by this side of the connection. This is used to determine whether or not data previously sent has successfully been received by the other end of the connection.

4-bit header length

This field contains the number of 32-bit words in the TCP header. If no options are present in the TCP header, this field is 5.

6-bit code bits

This field contains the six different code bits used to indicate various control information associated with the connection. The control bits are defined as follows:

Name	Bit	Meaning
URG	21	Urgent data present
ACK	20	Acknowledgement number is valid
PSH	19	Handle this data immediately
RST	18	Reset the connection
SYN	17	Synchronize sequence numbers (used to establish connection)
FIN	16	Sender is finished with transmit (used to close connection)

16-bit window

This field is used for flow control. It contains the amount of bytes the socket can currently receive. This basically is used for flow control. The sender is responsible for making sure the data to send will fit into the receiver's advertised window.

Header Field	Purpose
16-bit TCP checksum	This field contains the 16-bit checksum for the packet including the TCP header, the packet data area, and the pseudo IP header.
16-bit urgent pointer	This field contains the positive offset of the last byte of the urgent data. This field is only valid if the URG code bit is set in the header.

*All headers in the TCP/IP implementation are expected to be in **big endian** format. In this format, the most significant byte of the word resides at the lowest byte address.*

TCP Enable

Before TCP connections and packet transmissions are possible, the application must first enable TCP by calling the ***nx_tcp_enable*** service. After enabled, the application is free to access all TCP services.

TCP Socket Create

TCP sockets are created either during initialization or during runtime by application threads. The initial type of service, time to live, and window size are defined by the ***nx_tcp_socket_create*** service. There are no limits on the number of TCP sockets in an application.

TCP Checksum

TCP specifies a one's complement 16-bit checksum that covers the IP pseudo header, (consisting of the source IP address, destination IP address, and the protocol/length IP word), the TCP header, and the TCP packet data.

Certain network controllers are able to perform TCP checksum computation and validation in hardware.

For such systems, applications may want to use hardware checksum logic as much as possible to reduce runtime overhead. Applications may disable TCP checksum computation logic from the NetX library altogether at build time by defining ***`NX_DISABLE_TCP_TX_CHECKSUM`*** and ***`NX_DISABLE_TCP_RX_CHECKSUM`***. This way, the TCP checksum code is not compiled in.

TCP Port

A TCP port is a logical connection point in the TCP protocol. There are 65,535 valid ports in the TCP component of NetX, ranging from 1 through 0xFFFF. Unlike UDP in which data from one port can be sent to any other destination port, a TCP port is connected to another specific TCP port, and only when this connection is established can any data transfer take place—and only between the two ports making up the connection.

TCP ports are completely separate from UDP ports; e.g., UDP port number 1 has no relation to TCP port number 1.

Client-Server Model

To use TCP for data transfer, a connection must first be established between the two TCP sockets. The establishment of the connection is done in a client-server fashion. The client side of the connection is the side that initiates the connection, while the server side simply waits for client connection requests before any processing is done.

For multihomed devices, NetX automatically determines the source address to use for the connection, and the next hop address based on the destination IP address of the connection.

TCP Socket State Machine

The connection between two TCP sockets (one client and one server) is complex and is managed in a state machine manner. Each TCP socket starts in a CLOSED state. Through connection events each socket's state machine migrates into the ESTABLISHED state, which is where the bulk of the data transfer in TCP takes place. When one side of the connection no longer wishes to send data, it disconnects. After the other side disconnects, eventually the TCP socket returns to the CLOSED state. This process repeats each time a TCP client and server establish and close a connection. Figure 11 on page 97 shows the various states of the TCP state machine.

TCP Client Connection

As mentioned previously, the client side of the TCP connection initiates a connection request to a TCP server. Before a connection request can be made, TCP must be enabled on the client IP instance. In addition, the client TCP socket must next be created with the ***nx_tcp_socket_create*** service and bound to a port via the ***nx_tcp_client_socket_bind*** service.

After the client socket is bound, the ***nx_tcp_client_socket_connect*** service is used to establish a connection with a TCP server. Note the socket must be in a CLOSED state to initiate a connection attempt. Establishing the connection starts with NetX issuing a SYN packet and then waiting for a SYN ACK packet back from the server, which signifies acceptance of the connection request. After the SYN ACK is received, NetX responds with an ACK packet and promotes the client socket to the ESTABLISHED state.

TCP Client Disconnection

Closing the connection is accomplished by calling ***nx_tcp_socket_disconnect***. If no suspension is

FIGURE 11. States of the TCP State Machine

specified, the client socket sends a RST packet to the server socket and places the socket in the CLOSED state. Otherwise, if a suspension is requested, the full TCP disconnect protocol is performed, as follows:

- If the server previously initiated a disconnect request (the client socket has already received a FIN packet, responded with an ACK, and is in the CLOSE WAIT state), NetX promotes the client TCP socket state to the LAST ACK state and sends a FIN packet. It then waits for an ACK from the server before completing the disconnect and entering the CLOSED state.
- If on the other hand, the client is the first to initiate a disconnect request (the server has not disconnected and the socket is still in the ESTABLISHED state), NetX sends a FIN packet to initiate the disconnect and waits to receive a FIN and an ACK from the server before completing the disconnect and placing the socket in a CLOSED state.

If there are still packets on the socket transmit queue, NetX suspends for the specified timeout to allow the packets to be acknowledged. If the timeout expires, NetX empties the transmit queue of the client socket.

To unbind the port from the client socket, the application calls ***`nx_tcp_client_socket_unbind`***. The socket must be in a CLOSED state or in the process of disconnecting (i.e., TIMED WAIT state) before the port is released; otherwise, an error is returned.

Finally, if the application no longer needs the client socket, it calls ***`nx_tcp_socket_delete`*** to delete the socket.

TCP Server Connection

The server side of a TCP connection is passive; i.e., the server waits for a client to initiate connection request. To accept a client connection, TCP must first be enabled on the IP instance by calling the service ***nx_tcp_enable***. Next, the application must create a TCP socket using the ***nx_tcp_socket_create*** service.

The server socket must also be set up for listening for connection requests. This is achieved by using the ***nx_tcp_server_socket_listen*** service. This service places the server socket in the LISTEN state and binds the specified server port to the socket.

i

*To set a socket listen callback routine the application specifies the appropriate callback function for the ***tcp_listen_callback*** argument of the ***nx_tcp_server_socket_listen*** service. This application callback function is then executed by NetX whenever a new connection is requested on this server port. The processing in the callback is under application control.*

To accept client connection requests, the application calls the ***nx_tcp_server_socket_accept*** service. The server socket must either be in a LISTEN state or a SYN RECEIVED state (i.e., the server is in the LISTEN state and has received a SYN packet from a client requesting a connection) to call the accept service. A successful return status from ***nx_tcp_server_socket_accept*** indicates the connection has been set up and the server socket is in the ESTABLISHED state.

After the server socket has a valid connection, additional client connection requests are queued up to the depth specified by the ***listen_queue_size***, passed into the ***nx_tcp_server_socket_listen*** service. In order to process subsequent connections on a server port, the application must call ***nx_tcp_server_socket_relisten*** with an available

socket (i.e., a socket in a CLOSED state). Note that the same server socket could be used if the previous connection associated with the socket is now finished and the socket is in the CLOSED state.

TCP Server Disconnection

Closing the connection is accomplished by calling ***nx_tcp_socket_disconnect***. If no suspension is specified, the server socket sends a RST packet to the client socket and places the socket in the CLOSED state. Otherwise, if a suspension is requested, the full TCP disconnect protocol is performed, as follows:

- If the client previously initiated a disconnect request (the server socket has already received a FIN packet, responded with an ACK, and is in the CLOSE WAIT state), NetX promotes the TCP socket state to the LAST ACK state and sends a FIN packet. It then waits for an ACK from the client before completing the disconnect and entering the CLOSED state.
- If on the other hand, the server is the first to initiate a disconnect request (the client has not disconnected and the socket is still in the ESTABLISHED state), NetX sends a FIN packet to initiate the disconnect and waits to receive a FIN and an ACK from the client before completing the disconnect and placing the socket in a CLOSED state.

If there are still packets on the socket transmit queue, NetX suspends for the specified timeout to allow those packets to be acknowledged. If the timeout expires, NetX flushes the transmit queue of the server socket.

After the disconnect processing is complete and the server socket is in the CLOSED state, the application must call the ***nx_tcp_server_socket_unaccept*** service to end the association of this socket with the

server port. Note this service must be called by the application even if ***nx_tcp_socket_disconnect*** or ***nx_tcp_server_socket_accept*** return an error status. After the ***nx_tcp_server_socket_unaccept*** returns, the socket can be used as a client or server socket, or even deleted if it is no longer needed. If accepting another client connection on the same server port is desired, the ***nx_tcp_server_socket_relisten*** service should be called on this socket.

The following code segment illustrates the sequence of calls a typical TCP server uses:

```
/* Set up a previously created TCP socket to listen on
   port 12 */
nx_tcp_server_socket_listen()

/* Loop to make a (another) connection. */
while(1)
{
    /* Wait for a client socket connection request for
       100 ticks. */
    nx_tcp_server_socket_accept();

    /* (Send and receive TCP messages with the TCP
       client) */

    /* Disconnect the server socket. */
    nx_tcp_socket_disconnect();

    /* Remove this server socket from listening on the
       port. */
    nx_tcp_server_socket_unaccept(&server_socket);

    /* Set up server socket to relisten on the same port
       for the next client. */
    nx_tcp_server_socket_relisten();
}
```

MSS Validation

The Maximum Segment Size (MSS) is the maximum amount of bytes a TCP host can receive without being fragmented by the underlying IP layer. During TCP connection establishment phase, both ends exchanges its own TCP MSS value, so that the sender does not send a TCP data segment that is larger than the receiver's MSS. NetX TCP

module will optionally validate its peer's advertised MSS value before establishing a connection. By default NetX does not enable such a check. Applications wishing to perform MSS validation shall define ***NX_ENABLE_TCP_MSS_CHECKING*** when building the NetX library, and the minimum value shall be defined in ***NX_TCP_MSS_MINIMUM***. Incoming TCP connections with MSS values below ***NX_TCP_MSS_MINIMUM*** are dropped.

Stop Listening on a Server Port

If the application no longer wishes to listen for client connection requests on a server port that was previously specified by a call to the ***nx_tcp_server_socket_listen*** service, the application simply calls the ***nx_tcp_server_socket_unlisten*** service. This service places any socket waiting for a connection back in the CLOSED state and releases any queued client connection request packets.

TCP Window Size

During both the setup and data transfer phases of the connection, each port reports the amount of data it can handle, which is called its window size. As data are received and processed, this window size is adjusted dynamically. In TCP, a sender can only send an amount of data that fits into the receiver's window. In essence, the window size provides flow control for data transfer in each direction of the connection.

TCP Packet Send

Sending TCP data is easily accomplished by calling the ***nx_tcp_socket_send*** function. If the size of the data being transmitted is larger than the MSS value of the socket or the current peer receive window size, whichever is smaller, TCP internal logic carves off the data that fits into min (MSS, peer receive Window) for transmission. This service then builds a TCP header in front of the packet (including the

checksum calculation). If the receiver's window size is not zero, the caller will send as much data as it can to fill up the receiver window size. If the receive window becomes zero, the caller may suspend and wait for the receiver's window size to increase enough for this packet to be sent. At any given time, multiple threads may suspend while trying to send data through the same socket.

The TCP data residing in the NX_PACKET structure should reside on a long-word boundary. In addition, there needs to be sufficient space between the prepend pointer and the data start pointer to place the TCP, IP, and physical media headers.

TCP Packet Retransmit

Previously transmitted TCP packets sent actually stored internally until an ACK is returned from the other side of the connection. If transmitted data is not acknowledged within the timeout period, the stored packet is re-sent and the next timeout period is set. When an ACK is received, all packets covered by the acknowledgement number in the internal transmit queue are finally released.

Application shall not reuse the packet or alter the contents of the packet after nx_tcp_socket_send() returns with NX_SUCCESS. The transmitted packet is eventually released by NetX internal processing after the data is acknowledged by the other end.

TCP Keepalive

TCP Keepalive feature allows a socket to detect whether or not its peer disconnects without proper termination (for example, the peer crashed), or to prevent certain network monitoring facilities to terminate a connection for long periods of idle. TCP Keepalive works by periodically sending a TCP frame with no data, and the sequence number set to one less than the current sequence number. On receiving

such TCP Keepalive frame, the recipient, if still alive, responds with an ACK for its current sequence number. This completes the keepalive transaction.

By default the keepalive feature is not enabled. To use this feature, NetX library must be built with ***NX_ENABLE_TCP_KEEPALIVE*** defined. The symbol ***NX_TCP_KEEPALIVE_INITIAL*** specifies the number of seconds of inactivity before the keepalive frame is initiated.

TCP Packet Receive

The TCP receive packet processing (called from the IP helper thread) is responsible for handling various connection and disconnection actions as well as transmit acknowledge processing. In addition, the TCP receive packet processing is responsible for placing packets with receive data on the appropriate TCP socket's receive queue or delivering the packet to the first suspended thread waiting for a packet.

TCP Receive Notify

If the application thread needs to process received data from more than one socket, the ***nx_tcp_socket_receive_notify*** function should be used. This function registers a receive packet callback function for the socket. Whenever a packet is received on the socket, the callback function is executed.

The contents of the callback function are application-specific; however, the function would most likely contain logic to inform the processing thread that a packet is available on the corresponding socket.

Thread Suspension

As mentioned previously, application threads can suspend while attempting to receive data from a particular TCP port. After a packet is received on that port, it is given to the first thread suspended and that

thread is then resumed. An optional timeout is available when suspending on a TCP receive packet, a feature available for most NetX services.

Thread suspension is also available for connection (both client and server), client binding, and disconnection services.

TCP Socket Statistics and Errors

If enabled, the NetX TCP socket software keeps track of several statistics and errors that may be useful to the application. The following statistics and error reports are maintained for each IP/TCP instance:

- Total TCP Packets Sent
- Total TCP Bytes Sent
- Total TCP Packets Received
- Total TCP Bytes Received
- Total TCP Invalid Packets
- Total TCP Receive Packets Dropped
- Total TCP Receive Checksum Errors
- Total TCP Connections
- Total TCP Disconnections
- Total TCP Connections Dropped
- Total TCP Packet Retransmits
- TCP Socket Packets Sent
- TCP Socket Bytes Sent
- TCP Socket Packets Received
- TCP Socket Bytes Received
- TCP Socket Packet Retransmits
- TCP Socket Packets Queued
- TCP Socket Checksum Errors
- TCP Socket State
- TCP Socket Transmit Queue Depth
- TCP Socket Transmit Window Size
- TCP Socket Receive Window Size

All these statistics and error reports are available to the application with the ***nx_tcp_info_get*** service for total TCP statistics and the ***nx_tcp_socket_info_get*** service for TCP statistics per socket.

TCP Socket Control Block `NX_TCP_SOCKET`

The characteristics of each TCP socket are found in the associated `NX_TCP_SOCKET` control block, which contains useful information such as the link to the IP data structure, the network connection interface, the bound port, and the receive packet queue. This structure is defined in the *`nx_api.h`* file.

Description of NetX Services

This chapter contains a description of all NetX services in alphabetic order. Service names are designed so all similar services are grouped together. For example, all ARP services are found at the beginning of this chapter.

i Note that a BSD-Compatible Socket API is available for legacy application code that cannot take full advantage of the high-performance NetX API. Refer to Appendix D for more information on the BSD-Compatible Socket API.

In the “Return Values” section of each description, values in **BOLD** are not affected by the `NX_DISABLE_ERROR_CHECKING` option used to disable the API error checking, while values in non-bold are completely disabled. The “Allowed From” sections indicate from which each NetX service can be called.

`nx_arp_dynamic_entries_invalidate` 114
Invalidate all dynamic entries in the ARP cache

`nx_arp_dynamic_entry_set` 116
Set dynamic ARP entry

`nx_arp_enable` 118
Enable Address Resolution Protocol (ARP)

`nx_arp_gratuitous_send` 120
Send gratuitous ARP request

`nx_arp_hardware_address_find` 122
Locate physical hardware address given an IP address

`nx_arp_info_get` 124
Retrieve information about ARP activities

`nx_arp_ip_address_find` 126
Locate IP address given a physical address

`nx_arp_static_entries_delete` 128
Delete all static ARP entries

`nx_arp_static_entry_create` 130
Create static IP to hardware mapping in ARP cache

`nx_arp_static_entry_delete` 132
Delete static IP to hardware mapping in ARP cache

`nx_icmp_enable` 134
Enable Internet Control Message Protocol (ICMP)

`nx_icmp_info_get` 136
Retrieve information about ICMP activities

`nx_icmp_ping` 138
Send ping request to specified IP address

`nx_igmp_enable` 140
Enable Internet Group Management Protocol (IGMP)

`nx_igmp_info_get` 142
Retrieve information about IGMP activities

`nx_igmp_loopback_disable` 144
Disable IGMP loopback

`nx_igmp_loopback_enable` 146
Enable IGMP loopback

`nx_igmp_multicast_interface_join` 148
Join IP instance to specified multicast group via an interface

`nx_igmp_multicast_join` 150
Join IP instance to specified multicast group

`nx_igmp_multicast_leave` 152
Cause IP instance to leave specified multicast group

`nx_ip_address_change_notify` 154
Notify application if IP address changes

`nx_ip_address_get` 156
Retrieve IP address and network mask

`nx_ip_address_set` 158
Set IP address and network mask

`nx_ip_create` 160
Create an IP instance

`nx_ip_delete` 162
Delete previously created IP instance

`nx_ip_driver_direct_command` 164
Issue command to network driver

`nx_ip_driver_interface_direct_command` 166
Issue command to network driver

`nx_ip_forwarding_disable` 168
Disable IP packet forwarding

`nx_ip_forwarding_enable` 170
Enable IP packet forwarding

`nx_ip_fragment_disable` 172
Disable IP packet fragmenting

`nx_ip_fragment_enable` 174
Enable IP packet fragmenting

`nx_ip_gateway_address_set` 176
Set Gateway IP address

`nx_ip_info_get` 178
Retrieve information about IP activities

`nx_ip_interface_address_get` 180
Retrieve interface IP address

`nx_ip_interface_address_set` 182
Set interface IP address and network mask

`nx_ip_interface_attach` 184
Attach network interface to IP instance

`nx_ip_interface_info_get` 186
Retrieve network interface parameters

`nx_ip_interface_status_check` 188
Check status of an IP instance

`nx_ip_link_status_change_notify_set` 190
Set the link status change notify callback function

`nx_ip_raw_packet_disable` 192
Disable raw packet sending/receiving

`nx_ip_raw_packet_enable` 194
Enable raw packet processing

`nx_ip_raw_packet_interface_send` 196
Send raw IP packet through specified network interface

`nx_ip_raw_packet_receive` 198
Receive raw IP packet

`nx_ip_raw_packet_send` 200
Send raw IP packet

`nx_ip_static_route_add` 202
Add static route to the routing table

`nx_ip_static_route_delete` 204
Delete static route from routing table

`nx_ip_status_check` 206
Check status of an IP instance

`nx_packet_allocate` 208
Allocate packet from specified pool

`nx_packet_copy` 210
Copy packet

`nx_packet_data_append` 212
Append data to end of packet

`nx_packet_data_extract_offset` 214
Extract data from packet via an offset

`nx_packet_data_retrieve` 216
Retrieve data from packet

`nx_packet_length_get` 218
Get length of packet data

`nx_packet_pool_create` 220
Create packet pool in specified memory area

`nx_packet_pool_delete` 222
Delete previously created packet pool

`nx_packet_pool_info_get` 224
Retrieve information about a packet pool

`nx_packet_release` 226
Release previously allocated packet

`nx_packet_transmit_release` 228
Release a transmitted packet

`nx_rarp_disable` 230
Disable Reverse Address Resolution Protocol (RARP)

`nx_rarp_enable` 232
Enable Reverse Address Resolution Protocol (RARP)

`nx_rarp_info_get` 234
Retrieve information about RARP activities

`nx_system_initialize` 236
Initialize NetX System

`nx_tcp_client_socket_bind` 238
Bind client TCP socket to TCP port

`nx_tcp_client_socket_connect` 240
Connect client TCP socket

`nx_tcp_client_socket_port_get` 242
Get port number bound to client TCP socket

`nx_tcp_client_socket_unbind` 244
Unbind TCP client socket from TCP port

`nx_tcp_enable` 246
Enable TCP component of NetX

`nx_tcp_free_port_find` 248
Find next available TCP port

nx_tcp_info_get 250
Retrieve information about TCP activities
 nx_tcp_server_socket_accept 254
Accept TCP connection
 nx_tcp_server_socket_listen 258
Enable listening for client connection on TCP port
 nx_tcp_server_socket_relisten 262
Re-listen for client connection on TCP port
 nx_tcp_server_socket_unaccept 266
Remove socket association with listening port
 nx_tcp_server_socket_unlisten 270
Disable listening for client connection on TCP port
 nx_tcp_socket_bytes_available 274
Retrieves number of bytes available for retrieval
 nx_tcp_socket_create 276
Create TCP client or server socket
 nx_tcp_socket_delete 280
Delete TCP socket
 nx_tcp_socket_disconnect 282
Disconnect client and server socket connections
 nx_tcp_socket_disconnect_complete_notify 284
Install TCP disconnect complete notify callback function
 nx_tcp_socket_establish_notify 286
Set TCP establish notify callback function
 nx_tcp_socket_info_get 288
Retrieve information about TCP socket activities
 nx_tcp_socket_mss_get 292
Get MSS of socket
 nx_tcp_socket_mss_peer_get 294
Get MSS of the peer TCP socket
 nx_tcp_socket_mss_set 296
Set MSS of socket
 nx_tcp_socket_peer_info_get 298
Retrieve information about peer TCP socket
 nx_tcp_socket_receive 300
Receive data from TCP socket
 nx_tcp_socket_receive_notify 302
Notify application of received packets
 nx_tcp_socket_send 304
Send data through a TCP socket

`nx_tcp_socket_state_wait` 308
Wait for TCP socket to enter specific state

`nx_tcp_socket_timed_wait_callback` 310
Install callback for timed wait state

`nx_tcp_socket_transmit_configure` 312
Configure socket's transmit parameters

`nx_tcp_socket_window_update_notify_set` 314
Notify application of window size updates

`nx_udp_enable` 316
Enable UDP component of NetX

`nx_udp_free_port_find` 318
Find next available UDP port

`nx_udp_info_get` 320
Retrieve information about UDP activities

`nx_udp_packet_info_extract` 322
Extract network parameters from UDP packet

`nx_udp_socket_bind` 324
Bind UDP socket to UDP port

`nx_udp_socket_bytes_available` 326
Retrieves number of bytes available for retrieval

`nx_udp_socket_checksum_disable` 328
Disable checksum for UDP socket

`nx_udp_socket_checksum_enable` 330
Enable checksum for UDP socket

`nx_udp_socket_create` 332
Create UDP socket

`nx_udp_socket_delete` 334
Delete UDP socket

`nx_udp_socket_info_get` 336
Retrieve information about UDP socket activities

`nx_udp_socket_port_get` 338
Pick up port number bound to UDP socket

`nx_udp_socket_receive` 340
Receive datagram from UDP socket

`nx_udp_socket_receive_notify` 342
Notify application of each received packet

`nx_udp_socket_send` 344
Send a UDP Datagram

`nx_udp_socket_interface_send` 346
Send datagram through UDP socket

`nx_udp_socket_unbind` 348
Unbind UDP socket from UDP port
`nx_udp_source_extract` 350
Extract IP and sending port from UDP datagram

nx_arp_dynamic_entries_invalidate

Invalidate all dynamic entries in the ARP cache

Prototype

```
UINT nx_arp_dynamic_entries_invalidate(NX_IP *ip_ptr);
```

Description

This service invalidates all dynamic ARP entries currently in the ARP cache.

Parameters

ip_ptr	Pointer to previously created IP instance.
--------	--

Return Values

NX_SUCCESS	(0x00)	Successful ARP cache invalidate.
NX_NOT_ENABLED	(0x14)	ARP is not enabled.
NX_PTR_ERROR	(0x07)	Invalid IP address.
NX_CALLER_ERROR	(0x11)	Caller is not a thread.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Invalidate all dynamic entries in the ARP cache. */  
status = nx_arp_dynamic_entries_invalidate(&ip_0);  
  
/* If status is NX_SUCCESS the dynamic ARP entries were  
   successfully invalidated. */
```

See Also

`nx_arp_dynamic_entry_set`, `nx_arp_enable`, `nx_arp_gratuitous_send`,
`nx_arp_hardware_address_find`, `nx_arp_info_get`,
`nx_arp_ip_address_find`, `nx_arp_static_entries_delete`,
`nx_arp_static_entry_create`, `nx_arp_static_entry_delete`

nx_arp_dynamic_entry_set

Set dynamic ARP entry

Prototype

```
UINT nx_arp_dynamic_entry_set(NX_IP *ip_ptr,
                              ULONG ip_address,
                              ULONG physical_msw,
                              ULONG physical_lsw);
```

Description

This service allocates a dynamic entry from the ARP cache and sets up the specified IP to physical address mapping. If a zero physical address is specified, an actual ARP request is sent to the network in order to have the physical address resolved. Also note that this entry will be removed if ARP aging is active or if the ARP cache is exhausted and this is the least recently used ARP entry.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	IP address to map.
physical_msw	Top 16 bits (47-32) of the physical address.
physical_lsw	Lower 32 bits (31-0) of the physical address.

Return Values

NX_SUCCESS	(0x00)	Successful ARP dynamic entry set.
NX_NO_MORE_ENTRIES	(0x17)	No more ARP entries are available in the ARP cache.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_PTR_ERROR	(0x07)	Invalid IP instance pointer.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Setup a dynamic ARP entry on the previously created IP
   Instance 0. */
status = nx_arp_dynamic_entry_set(&ip_0, IP_ADDRESS(1,2,3,4),
                                   0x1022, 0x1234);

/* If status is NX_SUCCESS, there is now a dynamic mapping between
   the IP address of 1.2.3.4 and the physical hardware address of
   10:22:00:00:12:34. */
```

`nx_arp_gratuitous_send`, `nx_arp_hardware_address_find`,
`nx_arp_info_get`, `nx_arp_ip_address_find`, `nx_arp_static_entries_delete`,
`nx_arp_static_entry_create`, `nx_arp_static_entry_delete`

nx_arp_enable

Enable Address Resolution Protocol (ARP)

Prototype

```
UINT nx_arp_enable(NX_IP *ip_ptr, VOID *arp_cache_memory,
                  ULONG arp_cache_size);
```

Description

This service initializes the ARP component of NetX for the specific IP instance. ARP initialization includes setting up the ARP cache and various ARP processing routines necessary for sending and receiving ARP messages.

Parameters

ip_ptr	Pointer to previously created IP instance.
arp_cache_memory	Pointer to memory area to place ARP cache.
arp_cache_size	Each ARP entry is 52 bytes, the total number of ARP entries is, therefore, the size divided by 52.

Return Values

NX_SUCCESS	(0x00)	Successful ARP enable.
NX_PTR_ERROR	(0x07)	Invalid IP or cache memory pointer.
NX_SIZE_ERROR	(0x09)	User supplied ARP cache memory is too small.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_ALREADY_ENABLED	(0x15)	This component has already been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Enable ARP and supply 1024 bytes of ARP cache memory for
   previously created IP Instance ip_0. */
status = nx_arp_enable(&ip_0, (void *) pointer, 1024);

/* If status is NX_SUCCESS, ARP was successfully enabled for this IP
   instance.*/
```

See Also

`nx_arp_gratuitous_send`, `nx_arp_hardware_address_find`,
`nx_arp_info_get`, `nx_arp_ip_address_find`, `nx_arp_static_entries_delete`,
`nx_arp_static_entry_create`, `nx_arp_static_entry_delete`

nx_arp_gratuitous_send

Send gratuitous ARP request

Prototype

```
UINT nx_arp_gratuitous_send(NX_IP *ip_ptr,
                           VOID (*response_handler)
                           (NX_IP *ip_ptr,
                            NX_PACKET *packet_ptr));
```

Description

This service goes through all the physical interfaces to transmit gratuitous ARP requests as long as the interface IP address is valid. If an ARP response is subsequently received, the supplied response handler is called to process the response to the gratuitous ARP.

Parameters

ip_ptr	Pointer to previously created IP instance.
response_handler	Pointer to response handling function. If NX_NULL is supplied, responses are ignored.

Return Values

NX_SUCCESS	(0x00)	Successful gratuitous ARP send.
NX_NO_PACKET	(0x01)	No packet available.
NX_NOT_ENABLED	(0x14)	ARP is not enabled.
NX_IP_ADDRESS_ERROR	(0x21)	Current IP address is invalid.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Caller is not a thread.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Send gratuitous ARP without any response handler. */  
status = nx_arp_gratuitous_send(&ip_0, NX_NULL);  
  
/* If status is NX_SUCCESS the gratuitous ARP was successfully  
sent. */
```

`nx_arp_ip_address_find`, `nx_arp_static_entries_delete`,
`nx_arp_static_entry_create`, `nx_arp_static_entry_delete`

nx_arp_hardware_address_find

Locate physical hardware address given an IP address

Prototype

```
UINT nx_arp_hardware_address_find(NX_IP *ip_ptr,
                                  ULONG ip_address,
                                  ULONG *physical_msw,
                                  ULONG *physical_lsw);
```

Description

This service attempts to find a physical hardware address in the ARP cache that is associated with the supplied IP address.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	IP address to search for.
physical_msw	Pointer to the variable for returning the top 16 bits (47-32) of the physical address.
physical_lsw	Pointer to the variable for returning the lower 32 bits (31-0) of the physical address.

Return Values

NX_SUCCESS	(0x00)	Successful ARP hardware address find.
NX_ENTRY_NOT_FOUND	(0x16)	Mapping was not found in the ARP cache.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_PTR_ERROR	(0x07)	Invalid IP or memory pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Search for the hardware address associated with the IP address of
   1.2.3.4 in the ARP cache of the previously created IP
   Instance 0. */
status = nx_arp_hardware_address_find(&ip_0, IP_ADDRESS(1,2,3,4),
                                     &physical_msw,
                                     &physical_lsw);

/* If status is NX_SUCCESS, the variables physical_msw and
   physical_lsw contain the hardware address.*/
```

See Also

`nx_arp_ip_address_find`, `nx_arp_static_entries_delete`,
`nx_arp_static_entry_create`, `nx_arp_static_entry_delete`

nx_arp_info_get

Retrieve information about ARP activities

Prototype

```
UINT nx_arp_info_get(NX_IP *ip_ptr,
                    ULONG *arp_requests_sent,
                    ULONG *arp_requests_received,
                    ULONG *arp_responses_sent,
                    ULONG *arp_responses_received,
                    ULONG *arp_dynamic_entries,
                    ULONG *arp_static_entries,
                    ULONG *arp_aged_entries,
                    ULONG *arp_invalid_messages);
```

Description

This service retrieves information about ARP activities for the associated IP instance.

i

If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

ip_ptr	Pointer to previously created IP instance.
arp_requests_sent	Pointer to destination for the total ARP requests sent from this IP instance.
arp_requests_received	Pointer to destination for the total ARP requests received from the network.
arp_responses_sent	Pointer to destination for the total ARP responses sent from this IP instance.
arp_responses_received	Pointer to the destination for the total ARP responses received from the network.
arp_dynamic_entries	Pointer to the destination for the current number of dynamic ARP entries.
arp_static_entries	Pointer to the destination for the current number of static ARP entries.

arp_aged_entries	Pointer to the destination of the total number of ARP entries that have aged and became invalid.
arp_invalid_messages	Pointer to the destination of the total invalid ARP messages received.

Return Values

NX_SUCCESS	(0x00)	Successful ARP information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Pickup ARP information for ip_0. */
status = nx_arp_info_get(&ip_0, &arp_requests_sent,
                        &arp_requests_received,
                        &arp_responses_sent,
                        &arp_responses_received,
                        &arp_dynamic_entries,
                        &arp_static_entries,
                        &arp_aged_entries,
                        &arp_invalid_messages);

/* If status is NX_SUCCESS, the ARP information has been stored in
the supplied variables. */
```

 nx_arp_static_entry_delete

nx_arp_ip_address_find

Locate IP address given a physical address

Prototype

```
UINT nx_arp_ip_address_find(NX_IP *ip_ptr, ULONG *ip_address,
                             ULONG physical_msw, ULONG physical_lsw);
```

Description

This service attempts to find an IP address in the ARP cache that is associated with the supplied physical address.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	Pointer to return IP address, if one is found that has been mapped.
physical_msw	Top 16 bits (47-32) of the physical address to search for.
physical_lsw	Lower 32 bits (31-0) of the physical address to search for.

Return Values

NX_SUCCESS	(0x00)	Successful ARP IP address find
NX_ENTRY_NOT_FOUND	(0x16)	Mapping was not found in the ARP cache.
NX_PTR_ERROR	(0x07)	Invalid IP or memory pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_INVALID_PARAMETERS	(0x4D)	Physical_msw and physical_lsw are both 0.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Search for the IP address associated with the hardware address of
   0x0:0x01234 in the ARP cache of the previously created IP
   Instance ip_0. */
status = nx_arp_ip_address_find(&ip_0, &ip_address, 0x0, 0x1234);

/* If status is NX_SUCCESS, the variables ip_address contains the
   associated IP address. */
```

nx_arp_static_entry_delete

nx_arp_static_entries_delete

Delete all static ARP entries

Prototype

```
UINT nx_arp_static_entries_delete(NX_IP *ip_ptr);
```

Description

This service deletes all static entries in the ARP cache.

Parameters

ip_ptr	Pointer to previously created IP instance.
--------	--

Return Values

NX_SUCCESS	(0x00)	Static entries are deleted.
NX_PTR_ERROR	(0x07)	Invalid <i>ip_ptr</i> pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Delete all the static ARP entries for IP Instance 0, assuming
   "ip_0" is the NX_IP structure for IP Instance 0. */
status = nx_arp_static_entries_delete(&ip_0);

/* If status is NX_SUCCESS all static ARP entries in the ARP cache
   have been deleted. */
```

`nx_arp_ip_address_find`, `nx_arp_static_entry_create`,
`nx_arp_static_entry_delete`

nx_arp_static_entry_create

Create static IP to hardware mapping in ARP cache

Prototype

```
UINT nx_arp_static_entry_create(NX_IP *ip_ptr,
                                ULONG ip_address,
                                ULONG physical_msw,
                                ULONG physical_lsw);
```

Description

This service creates a static IP-to-physical address mapping in the ARP cache for the specified IP instance. Static ARP entries are not subject to ARP periodic updates.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	IP address to map.
physical_msw	Top 16 bits (47-32) of the physical address to map.
physical_lsw	Lower 32 bits (31-0) of the physical address to map.

Return Values

NX_SUCCESS	(0x00)	Successful ARP static entry create.
NX_NO_MORE_ENTRIES	(0x17)	No more ARP entries are available in the ARP cache.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_INVALID_PARAMETERS	(0x4D)	Physical_msw and physical_lsw are both 0.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Create a static ARP entry on the previously created IP
   Instance 0. */
status = nx_arp_static_entry_create(&ip_0, IP_ADDRESS(1,2,3,4),
                                     0x0, 0x1234);

/* If status is NX_SUCCESS, there is now a static mapping between
   the IP address of 1.2.3.4 and the physical hardware address of
   00:00:00:00:12:34. */
```

nx_arp_static_entry_delete

Delete static IP to hardware mapping in ARP cache

Prototype

```
UINT nx_arp_static_entry_delete(NX_IP *ip_ptr,
                                ULONG ip_address,
                                ULONG physical_msw,
                                ULONG physical_lsw);
```

Description

This service finds and deletes a previously created static IP-to-physical address mapping in the ARP cache for the specified IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	IP address that was mapped statically.
physical_msw	Top 16 bits (47 - 32) of the physical address that was mapped statically.
physical_lsw	Lower 32 bits (31 - 0) of the physical address that was mapped statically.

Return Values

NX_SUCCESS	(0x00)	Successful ARP static entry delete.
NX_ENTRY_NOT_FOUND	(0x16)	Static ARP entry was not found in the ARP cache.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_INVALID_PARAMETERS	(0x4D)	Physical_msw and physical_lsw are both 0.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Delete a static ARP entry on the previously created IP
   instance ip_0. */
status = nx_arp_static_entry_delete(&ip_0, IP_ADDRESS(1,2,3,4),
                                     0x0, 0x1234);

/* If status is NX_SUCCESS, the previously created static ARP entry
   was successfully deleted. */
```

nx_arp_static_entry_create

Example

```
/* Enable ICMP on the previously created IP Instance ip_0. */
status = nx_icmp_enable(&ip_0);

/* If status is NX_SUCCESS, ICMP is enabled. */
```

See Also

`nx_icmp_info_get`, `nx_icmp_ping`

nx_icmp_info_get

Retrieve information about ICMP activities

Prototype

```
UINT nx_icmp_info_get(NX_IP *ip_ptr,
                     ULONG *pings_sent,
                     ULONG *ping_timeouts,
                     ULONG *ping_threads_suspended,
                     ULONG *ping_responses_received,
                     ULONG *icmp_checksum_errors,
                     ULONG *icmp_unhandled_messages);
```

Description

This service retrieves information about ICMP activities for the specified IP instance.

i If a destination pointer is `NX_NULL`, that particular information is not returned to the caller.

Parameters

<code>ip_ptr</code>	Pointer to previously created IP instance.
<code>pings_sent</code>	Pointer to destination for the total number of pings sent.
<code>ping_timeouts</code>	Pointer to destination for the total number of ping timeouts.
<code>ping_threads_suspended</code>	Pointer to destination of the total number of threads suspended on ping requests.
<code>ping_responses_received</code>	Pointer to destination of the total number of ping responses received.
<code>icmp_checksum_errors</code>	Pointer to destination of the total number of ICMP checksum errors.
<code>icmp_unhandled_messages</code>	Pointer to destination of the total number of un-handled ICMP messages.

Return Values

NX_SUCCESS	(0x00)	Successful ICMP information retrieval.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Retrieve ICMP information from previously created IP
   instance ip_0. */
status = nx_icmp_info_get(&ip_0, &pings_sent, &ping_timeouts,
                        &ping_threads_suspended,
                        &ping_responses_received,
                        &icmp_checksum_errors,
                        &icmp_unhandled_messages);

/* If status is NX_SUCCESS, ICMP information was retrieved. */
```

See Also

`nx_icmp_enable`, `nx_icmp_ping`

nx_icmp_ping

Send ping request to specified IP address

Prototype

```
UINT nx_icmp_ping(NX_IP *ip_ptr,
                  ULONG ip_address,
                  CHAR *data, ULONG data_size,
                  NX_PACKET **response_ptr,
                  ULONG wait_option);
```

Description

This service sends a ping request to the specified IP address and waits for the specified amount of time for a ping response message. If no response is received, an error is returned. Otherwise, the entire response message is returned in the variable pointed to by response_ptr.

If NX_SUCCESS is returned, the application is responsible for releasing the received packet after it is no longer needed.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	IP address, in host byte order, to ping.
data	Pointer to data area for ping message.
data_size	Number of bytes in the ping data
response_ptr	Pointer to packet pointer to return the ping response message in.
wait_option	Defines how long to wait for a ping response. wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful ping. Response message pointer was placed in
------------	--------	---

		the variable pointed to by response_ptr.
NX_NO_PACKET	(0x01)	Unable to allocate a ping request packet.
NX_OVERFLOW	(0x03)	Specified data area exceeds the default packet size for this IP instance.
NX_NO_RESPONSE	(0x29)	Requested IP did not respond.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_PTR_ERROR	(0x07)	Invalid IP or response pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Issue a ping to IP address 1.2.3.5 from the previously created IP
   Instance ip_0. */
status = nx_icmp_ping(&ip_0, IP_ADDRESS(1,2,3,5), "abcd", 4,
                     &response_ptr, 10);

/* If status is NX_SUCCESS, a ping response was received from IP
   address 1.2.3.5 and the response packet is contained in the
   packet pointed to by response_ptr. It should have the same "abcd"
   four bytes of data. */

```

See Also

nx_icmp_enable, nx_icmp_info_get

Example

```
/* Enable IGMP on the previously created IP Instance ip_0. */  
status = nx_igmp_enable(&ip_0);  
  
/* If status is NX_SUCCESS, IGMP is enabled. */
```

`nx_igmp_multicast_join`, `nx_igmp_multicast_leave`

nx_igmp_info_get

Retrieve information about IGMP activities

Prototype

```
UINT nx_igmp_info_get(NX_IP *ip_ptr,
                      ULONG *igmp_reports_sent,
                      ULONG *igmp_queries_received,
                      ULONG *igmp_checksum_errors,
                      ULONG *current_groups_joined);
```

Description

This service retrieves information about IGMP activities for the specified IP instance.

i If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

ip_ptr	Pointer to previously created IP instance.
igmp_reports_sent	Pointer to destination for the total number of ICMP reports sent.
igmp_queries_received	Pointer to destination for the total number of queries received by multicast router.
igmp_checksum_errors	Pointer to destination of the total number of IGMP checksum errors on receive packets.
current_groups_joined	Pointer to destination of the current number of groups joined through this IP instance.

Return Values

NX_SUCCESS	(0x00)	Successful IGMP information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Retrieve IGMP information from previously created IP Instance
ip_0. */
status = nx_igmp_info_get(&ip_0, &igmp_reports_sent,
                          &igmp_queries_received,
                          &igmp_checksum_errors,
                          &current_groups_joined);

/* If status is NX_SUCCESS, IGMP information was retrieved. */
```

`nx_igmp_multicast_interface_join`, `nx_igmp_multicast_join`,
`nx_igmp_multicast_leave`

nx_igmp_loopback_enable

Enable IGMP loopback

Prototype

```
UINT nx_igmp_loopback_enable(NX_IP *ip_ptr);
```

Description

This service enables IGMP loopback for all subsequent multicast groups joined.

Parameters

ip_ptr Pointer to previously created IP instance.

Return Values

NX_SUCCESS	(0x00)	Successful IGMP loopback disable.
NX_NOT_ENABLED	(0x14)	IGMP is not enabled.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Caller is not a thread or initialization.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Enable IGMP loopback for all subsequent multicast
   groups joined. */
status = nx_igmp_loopback_enable(&ip_0);

/* If status is NX_SUCCESS IGMP loopback is enabled. */
```

See Also

`nx_igmp_enable`, `nx_igmp_info_get`, `nx_igmp_loopback_disable`,
`nx_igmp_multicast_interface_join`, `nx_igmp_multicast_join`,
`nx_igmp_multicast_leave`

nx_igmp_multicast_interface_join

Join IP instance to specified multicast group via an interface

Prototype

```
UINT nx_igmp_multicast_interface_join(NX_IP *ip_ptr,
                                       ULONG group_address,
                                       UINT interface_index)
```

Description

This service joins an IP instance to the specified multicast group via a specified network interface. An internal counter is maintained to keep track of the number of times the same group has been joined. After joining the multicast group, the IGMP component will allow reception of IP packets with this group address via the specified network interface and also report to routers that this IP is a member of this multicast group. The IGMP membership join, report, and leave messages are also sent via the specified network interface.

Parameters

ip_ptr	Pointer to previously created IP instance.
group_address	Class D IP multicast group address to join in host byte order.
interface_index	Index of the Interface attached to the NetX instance.

Return Values

NX_SUCCESS	(0x00)	Successful multicast group join.
NX_NO_MORE_ENTRIES	(0x17)	No more multicast groups can be joined, maximum exceeded.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_INVALID_INTERFACE	(0x4C)	Device index points to an invalid network interface.
NX_IP_ADDRESS_ERROR	(0x21)	Multicast group address provided is not a valid class D address.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

NX_NOT_ENABLED	(0x14)	IP multicast support is not enabled.
----------------	--------	--------------------------------------

Allowed From

Threads

Preemption Possible

No

Example

```

/* Previously created IP Instance joins the multicast group
   244.0.0.200, via the interface at index 1 in the IP interface
   list. */
#define INTERFACE_INDEX 1
status = nx_igmp_multicast_interface_join
                                   (&ip, IP_ADDRESS(244,0,0,200),
                                   INTERFACE_INDEX);

/* If status is NX_SUCCESS, the IP instance has successfully joined
   the multicast group. */

```

See Also

nx_igmp_enable, nx_igmp_info_get, nx_igmp_loopback_disable,
 nx_igmp_loopback_enable, nx_igmp_multicast_join,
 nx_igmp_multicast_leave

nx_igmp_multicast_join

Join IP instance to specified multicast group

Prototype

```
UINT nx_igmp_multicast_join(NX_IP *ip_ptr, ULONG group_address);
```

Description

This service joins an IP instance to the specified multicast group. An internal counter is maintained to keep track of the number of times the same group has been joined. The driver is commanded to send an IGMP report if this is the first join request out on the network indicating the host's intention to join the group. After joining, the IGMP component will allow reception of IP packets with this group address and report to routers that this IP is a member of this multicast group.

i To join a multicast group on a non-primary device, use the service ***nx_igmp_multicast_interface_join***.

Parameters

ip_ptr	Pointer to previously created IP instance.
group_address	Class D IP multicast group address to join.

Return Values

NX_SUCCESS	(0x00)	Successful multicast group join.
NX_NO_MORE_ENTRIES	(0x17)	No more multicast groups can be joined, maximum exceeded.
NX_INVALID_INTERFACE	(0x4C)	Device index points to an invalid network interface.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP group address.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Previously created IP Instance ip_0 joins the multicast group
   224.0.0.200. */
status = nx_igmp_multicast_join(&ip_0, IP_ADDRESS(224,0,0,200));

/* If status is NX_SUCCESS, this IP instance has successfully
   joined the multicast group 224.0.0.200. */
```

See Also

nx_igmp_loopback_enable, nx_igmp_multicast_interface_join,
nx_igmp_multicast_leave

nx_igmp_multicast_leave

Cause IP instance to leave specified multicast group

Prototype

```
UINT nx_igmp_multicast_leave(NX_IP *ip_ptr, ULONG group_address);
```

Description

This service causes an IP instance to leave the specified multicast group, if the number of leave requests matches the number of join requests. Otherwise, the internal join count is simply decremented.

Parameters

ip_ptr	Pointer to previously created IP instance.
group_address	Multicast group to leave.

Return Values

NX_SUCCESS	(0x00)	Successful multicast group join.
NX_ENTRY_NOT_FOUND	(0x16)	Previous join request was not found.
NX_INVALID_INTERFACE	(0x4C)	Device index points to an invalid network interface.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP group address.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Cause IP instance to leave the multicast group 224.0.0.200. */
status = nx_igmp_multicast_leave(&ip_0, IP_ADDRESS(224,0,0,200));

/* If status is NX_SUCCESS, this IP instance has successfully left
the multicast group 224.0.0.200. */
```

nx_ip_address_change_notify

Notify application if IP address changes

Prototype

```
UINT nx_ip_address_change_notify(NX_IP *ip_ptr,
                                VOID(*change_notify)(NX_IP *,
                                VOID *),VOID *additional_info);
```

Description

This service registers an application notification function that is called whenever the IP address is changed.

Parameters

ip_ptr	Pointer to previously created IP instance.
change_notify	Pointer to IP change notification function. If this parameter is NX_NULL, IP address change notification is disabled.
additional_info	Pointer to optional additional information that is also supplied to the notification function when the IP address is changed.

Return Values

NX_SUCCESS	(0x00)	Successful IP address change notification.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Register the function "my_ip_changed" to be called whenever the
   IP address is changed. */
status = nx_ip_address_change_notify(&ip_0, my_ip_changed,
                                     NX_NULL);

/* If status is NX_SUCCESS, the "my_ip_changed" function will be
   called whenever the IP address changes. */
```

See Also

`nx_ip_status_check`, `nx_system_initialize`

nx_ip_address_get

Retrieve IP address and network mask

Prototype

```
UINT nx_ip_address_get(NX_IP *ip_ptr,
                      ULONG *ip_address,
                      ULONG *network_mask);
```

Description

This service retrieves IP address and its subnet mask of the primary network interface.

i To obtain information of the secondary device, use the service **nx_ip_interface_address_get**.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	Pointer to destination for IP address.
network_mask	Pointer to destination for network mask.

Return Values

NX_SUCCESS	(0x00)	Successful IP address get.
NX_PTR_ERROR	(0x07)	Invalid IP or return variable pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Get the IP address and network mask from the previously created
   IP Instance ip_0. */
status = nx_ip_address_get(&ip_0, &ip_address, &network_mask);

/* If status is NX_SUCCESS, the variables ip_address and
   network_mask contain the IP and network mask respectively. */
```

nx_ip_address_set

Set IP address and network mask

Prototype

```
UINT nx_ip_address_set(NX_IP *ip_ptr,
                      ULONG ip_address,
                      ULONG network_mask);
```

Description

This service sets IP address and network mask for the primary network interface.

i To set IP address and network mask for the secondary device, use the service **nx_ip_interface_address_set**.

Parameters

ip_ptr	Pointer to previously created IP instance.
ip_address	New IP address.
network_mask	New network mask.

Return Values

NX_SUCCESS	(0x00)	Successful IP address set.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Set the IP address and network mask to 1.2.3.4 and 0xFFFFFFFF00 for
   the previously created IP Instance ip_0. */
status = nx_ip_address_set(&ip_0, IP_ADDRESS(1,2,3,4),
                           0xFFFFFFFF00UL);

/* If status is NX_SUCCESS, the IP instance now has an IP address of
   1.2.3.4 and a network mask of 0xFFFFFFFF00. */
```

`nx_ip_fragment_enable`, `nx_ip_info_get`, `nx_ip_status_check`,
`nx_system_initialize`

nx_ip_create

Create an IP instance

Prototype

```
UINT nx_ip_create(NX_IP *ip_ptr, CHAR *name, ULONG ip_address,
                  ULONG network_mask, NX_PACKET_POOL *default_pool,
                  VOID (*ip_network_driver)(NX_IP_DRIVER *),
                  VOID *memory_ptr, ULONG memory_size,
                  UINT priority);
```

Description

This service creates an IP instance with the user supplied IP address and network driver. In addition, the application must supply a previously created packet pool for the IP instance to use for internal packet allocation. Note that the supplied application network driver is not called until this IP's thread executes.

Parameters

ip_ptr	Pointer to control block to create a new IP instance.
name	Name of this new IP instance.
ip_address	IP address for this new IP instance.
network_mask	Mask to delineate the network portion of the IP address for sub-netting and super-netting uses.
default_pool	Pointer to control block of previously created NetX packet pool.
ip_network_driver	User-supplied network driver used to send and receive IP packets.
memory_ptr	Pointer to memory area for the IP helper thread's stack area.
memory_size	Number of bytes in the memory area for the IP helper thread's stack.
priority	Priority of IP helper thread.

Return Values

NX_SUCCESS	(0x00)	Successful IP instance creation.
------------	--------	----------------------------------

NX_NOT_IMPLEMENTED	(0x4A)	NetX library is configured incorrectly.
NX_PTR_ERROR	(0x07)	Invalid IP, network driver function pointer, packet pool, or memory pointer.
NX_SIZE_ERROR	(0x09)	The supplied stack size is too small.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_IP_ADDRESS_ERROR	(0x21)	The supplied IP address is invalid.
NX_OPTION_ERROR	(0x21)	The supplied IP thread priority is invalid.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Create an IP instance with an IP address of 1.2.3.4 and a network
mask of 0xFFFFFFFFUL. The "ethernet_driver" specifies the entry
point of the application specific network driver and the
"stack_memory_ptr" specifies the start of a 1024 byte memory
area that is used for this IP instance's helper thread. */
status = nx_ip_create(&ip_0, "NetX IP Instance ip_0",
                     IP_ADDRESS(1, 2, 3, 4),
                     0xFFFFFFFFUL, &pool_0, ethernet_driver,
                     stack_memory_ptr, 1024, 1);

/* If status is NX_SUCCESS, the IP instance has been created. */
```

nx_ip_driver_direct_command

Issue command to network driver

Prototype

```
UINT nx_ip_driver_direct_command(NX_IP *ip_ptr,
                                UINT command,
                                ULONG *return_value_ptr);
```

Description

This service provides a direct interface to the application's primary network interface driver specified during the **nx_ip_create** call. Application-specific commands can be used providing their numeric value is greater than or equal to NX_LINK_USER_COMMAND.

*To issue command for the secondary device, use the **nx_ip_driver_interface_direct_command** service.*

Parameters

ip_ptr	Pointer to previously created IP instance.
command	Numeric command code. Standard commands are defined as follows: <div><div>NX_LINK_GET_STATUS(10)</div><div>NX_LINK_GET_SPEED(11)</div><div>NX_LINK_GET_DUPLEX_TYPE(12)</div><div>NX_LINK_GET_ERROR_COUNT(13)</div><div>NX_LINK_GET_RX_COUNT(14)</div><div>NX_LINK_GET_TX_COUNT(15)</div><div>NX_LINK_GET_ALLOC_ERRORS(16)</div><div>NX_LINK_USER_COMMAND(50)</div></div>
return_value_ptr	Pointer to return variable in the caller.

Return Values

NX_SUCCESS	(0x00)	Successful network driver direct command.
NX_UNHANDLED_COMMAND	(0x44)	Unhandled or unimplemented network driver command.

NX_PTR_ERROR	(0x07)	Invalid IP or return value pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_INVALID_INTERFACE	(0x4C)	Invalid interface index.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Make a direct call to the application-specific network driver
   for the previously created IP instance. For this example, the
   network driver is interrogated for the link status. */
status = nx_ip_driver_direct_command(&ip_0, NX_LINK_GET_STATUS,
                                     &link_status);

/* If status is NX_SUCCESS, the link_status variable contains a
   NX_TRUE or NX_FALSE value representing the status of the
   physical link. */
```

`nx_ip_status_check`, `nx_system_initialize`

nx_ip_driver_interface_direct_command

Issue command to network driver

Prototype

```
UINT nx_ip_driver_interface_direct_command(NX_IP *ip_ptr,
                                           UINT command,
                                           UINT interface_index,
                                           ULONG *return_value_ptr);
```

Description

This service provides a direct command to the application's network device driver in the IP instance. Application-specific commands can be used providing their numeric value is greater than or equal to *NX_LINK_USER_COMMAND*.

Parameters

ip_ptr	Pointer to previously created IP instance.
command	Numeric command code. Standard commands are defined as follows: <div><div>NX_LINK_GET_STATUS(10)</div><div>NX_LINK_GET_SPEED(11)</div><div>NX_LINK_GET_DUPLEX_TYPE(12)</div><div>NX_LINK_GET_ERROR_COUNT(13)</div><div>NX_LINK_GET_RX_COUNT(14)</div><div>NX_LINK_GET_TX_COUNT(15)</div><div>NX_LINK_GET_ALLOC_ERRORS(16)</div><div>NX_LINK_USER_COMMAND(50)</div></div>
interface_index	Index of the network interface the command should be sent to.
return_value_ptr	Pointer to return variable in the caller.

Return Values

NX_SUCCESS	(0x00)	Successful network driver direct command.
NX_UNHANDLED_COMMAND	(0x44)	Unhandled or unimplemented network driver command.
NX_INVALID_INTERFACE	(0x4C)	Invalid interface index

NX_PTR_ERROR	(0x07)	Invalid IP or return value pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Make a direct call to the application-specific network driver
   for the previously created IP instance. For this example, the
   network driver is interrogated for the link status. */

/* Set the interface index to the primary device. */
UINT interface_index = 0;

status = nx_ip_driver_interface_direct_command(&ip_0,
                                              NX_LINK_GET_STATUS,
                                              interface_index,
                                              &link_status);

/* If status is NX_SUCCESS, the link_status variable contains a
   NX_TRUE or NX_FALSE value representing the status of the
   physical link. */

`nx_ip_gateway_address_set`

Set Gateway IP address

Prototype

```
UINT nx_ip_gateway_address_set(NX_IP *ip_ptr, ULONG ip_address);
```

Description

This service sets the IP gateway IP address. All out-of-network traffic are routed to this gateway for transmission. The gateway must be directly accessible through one of the network interfaces.

Parameters

<code>ip_ptr</code>	Pointer to previously created IP instance.
<code>ip_address</code>	IP address of the gateway.

Return Values

<code>NX_SUCCESS</code>	(0x00)	Successful Gateway IP address set.
<code>NX_PTR_ERROR</code>	(0x07)	Invalid IP instance pointer.
<code>NX_IP_ADDRESS_ERROR</code>	(0x21)	Invalid IP address.
<code>NX_CALLER_ERROR</code>	(0x11)	Invalid caller of this service.

Allowed From

Initialization, thread

Preemption Possible

No

Example

```
/* Setup the Gateway address for previously created IP
   Instance ip_0. */
status = nx_ip_gateway_address_set(&ip_0, IP_ADDRESS(1,2,3,99));

/* If status is NX_SUCCESS, all out-of-network send requests are
   routed to 1.2.3.99. */
```

See Also

`nx_ip_info_get`, `nx_ip_static_route_add`, `nx_ip_static_route_delete`

nx_ip_info_get

Retrieve information about IP activities

Prototype

```
UINT nx_ip_info_get(NX_IP *ip_ptr,
                   ULONG *ip_total_packets_sent,
                   ULONG *ip_total_bytes_sent,
                   ULONG *ip_total_packets_received,
                   ULONG *ip_total_bytes_received,
                   ULONG *ip_invalid_packets,
                   ULONG *ip_receive_packets_dropped,
                   ULONG *ip_receive_checksum_errors,
                   ULONG *ip_send_packets_dropped,
                   ULONG *ip_total_fragments_sent,
                   ULONG *ip_total_fragments_received);
```

Description

This service retrieves information about IP activities for the specified IP instance.

i If a destination pointer is `NX_NULL`, that particular information is not returned to the caller.

Parameters

<code>ip_ptr</code>	Pointer to previously created IP instance.
<code>ip_total_packets_sent</code>	Pointer to destination for the total number of IP packets sent.
<code>ip_total_bytes_sent</code>	Pointer to destination for the total number of bytes sent.
<code>ip_total_packets_received</code>	Pointer to destination of the total number of IP receive packets.
<code>ip_total_bytes_received</code>	Pointer to destination of the total number of IP bytes received.
<code>ip_invalid_packets</code>	Pointer to destination of the total number of invalid IP packets.
<code>ip_receive_packets_dropped</code>	Pointer to destination of the total number of receive packets dropped.
<code>ip_receive_checksum_errors</code>	Pointer to destination of the total number of checksum errors in receive packets.
<code>ip_send_packets_dropped</code>	Pointer to destination of the total number of send packets dropped.

<code>ip_total_fragments_sent</code>	Pointer to destination of the total number of fragments sent.
<code>ip_total_fragments_received</code>	Pointer to destination of the total number of fragments received.

Return Values

<code>NX_SUCCESS</code>	(0x00)	Successful IP information retrieval.
<code>NX_CALLER_ERROR</code>	(0x11)	Invalid caller of this service.
<code>NX_PTR_ERROR</code>	(0x07)	Invalid IP pointer.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Retrieve IP information from previously created IP
   Instance 0. */
status = nx_ip_info_get(&ip_0,
                        &ip_total_packets_sent,
                        &ip_total_bytes_sent,
                        &ip_total_packets_received,
                        &ip_total_bytes_received,
                        &ip_invalid_packets,
                        &ip_receive_packets_dropped,
                        &ip_receive_checksum_errors,
                        &ip_send_packets_dropped,
                        &ip_total_fragments_sent,
                        &ip_total_fragments_received);

/* If status is NX_SUCCESS, IP information was retrieved. */
```

nx_ip_interface_address_get

Retrieve interface IP address

Prototype

```
UINT nx_ip_interface_address_get (NX_IP *ip_ptr,
                                  UINT   interface_index,
                                  ULONG  *ip_address,
                                  ULONG  *network_mask)
```

Description

This service retrieves the IP address of a specified network interface.

The specified device, if not the primary device, must be previously attached to the IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.
interface_index	Interface index, the same value as the index to the network interface attached to the IP instance.
ip_address	Pointer to destination for the device interface IP address.
network_mask	Pointer to destination for the device interface network mask.

Return Values

NX_SUCCESS	(0x00)	Successful IP address get.
NX_INVALID_INTERFACE	(0x4C)	Specified network interface is invalid.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
#define INTERFACE_INDEX 1
/* Get device IP address and network mask for the specified
   interface index 1 in IP instance list of interfaces). */
status = nx_ip_interface_address_get(ip_ptr, INTERFACE_INDEX,
                                     &ip_address,
                                     &network_mask);

/* If status is NX_SUCCESS the interface address was successfully
   retrieved. */
```

`nx_ip_interface_address_set`, `nx_ip_interface_attach`,
`nx_ip_interface_info_get`, `nx_ip_interface_status_check`,
`nx_ip_link_status_change_notify_set`

nx_ip_interface_address_set

Set interface IP address and network mask

Prototype

```
UINT nx_ip_interface_address_set(NX_IP *ip_ptr,
                                UINT interface_index,
                                ULONG ip_address,
                                ULONG network_mask)
```

Description

This service sets the IP address and network mask for the specified IP interface.

The specified interface must be previously attached to the IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.
interface_index	Index of the interface attached to the NetX instance.
ip_address	New network interface IP address.
network_mask	New interface network mask.

Return Values

NX_SUCCESS	(0x00)	Successful IP address set.
NX_INVALID_INTERFACE	(0x4C)	Specified network interface is invalid.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid pointers.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
#define INTERFACE_INDEX 1
/* Set device IP address and network mask for the specified
   interface index 1 in IP instance list of interfaces). */
status = nx_ip_interface_address_set(ip_ptr, INTERFACE_INDEX,
                                     ip_address,
                                     network_mask);

/* If status is NX_SUCCESS the interface IP address and mask was
   successfully set. */
```

See Also

`nx_ip_interface_address_get`, `nx_ip_interface_attach`,
`nx_ip_interface_info_get`, `nx_ip_interface_status_check`,
`nx_ip_link_status_change_notify_set`

nx_ip_interface_attach

Attach network interface to IP instance

Prototype

```
UINT nx_ip_interface_attach(NX_IP*ip_ptr, CHAR*interface_name,
                           ULONG ip_address,
                           ULONG network_mask,
                           VOID(*ip_link_driver)
                           (struct NX_IP_DRIVER_STRUCT *));
```

Description

This service adds a physical network interface to the IP interface. Note the IP instance is created with the primary interface so each additional interface is secondary to the primary interface. The total number of network interfaces attached to the IP instance (including the primary interface) cannot exceed **NX_MAX_PHYSICAL_INTERFACES**.

If the IP thread has not been running yet, the secondary interfaces will be initialized as part of the IP thread startup process that initializes all physical interfaces.

If the IP thread is not running yet, the secondary interface is initialized as part of the **nx_ip_interface_attach** service.

ip_ptr must point to a valid NetX IP structure.

NX_MAX_PHYSICAL_INTERFACES must be configured for the number of network interfaces for the IP instance. The default value is one.

Parameters

ip_ptr	Pointer to previously created IP instance.
interface_name	Pointer to interface name string.
ip_address	Device IP address in host byte order.
network_mask	Device network mask in host byte order.
ip_link_driver	Ethernet driver for the interface.

Return Values

NX_SUCCESS	(0x00)	Entry is added to static routing table.
-------------------	--------	---

NX_NO_MORE_ENTRIES	(0x17)	Max number of interfaces. NX_MAX_PHYSICAL_INTERFACES is exceeded.
NX_DUPLICATED_ENTRY	(0x52)	The supplied IP address is already used on this IP instance.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid pointer input.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address input.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Attach secondary device for device IP address 192.168.1.68 with
   the specified Ethernet driver. */
status = nx_ip_interface_attach(ip_ptr, "secondary_port",
                                IP_ADDRESS(192,168,1,68),
                                0xFFFFFFFFUL,
                                nx_etherDriver);

/* If status is NX_SUCCESS the interface was successfully added to
   the IP instance interface table. */
```

See Also

`nx_ip_interface_address_get`, `nx_ip_interface_address_set`,
`nx_ip_interface_info_get`, `nx_ip_interface_status_check`,
`nx_ip_link_status_change_notify_set`

nx_ip_interface_info_get

Retrieve network interface parameters

Prototype

```
UINT nx_ip_interface_info_get(NX_IP *ip_ptr,
                              UINT interface_index,
                              CHAR **interface_name,
                              ULONG *ip_address,
                              ULONG *network_mask,
                              ULONG *mtu_size,
                              ULONG *physical_address_msw,
                              ULONG *physical_address_lsw);
```

Description

This service retrieves information on network parameters for the specified network interface. All data are retrieved in host byte order.

 *ip_ptr must point to a valid NetX IP structure. The specified interface, if not the primary interface, must be previously attached to the IP instance.*

Parameters

ip_ptr	Pointer to previously created IP instance.
interface_index	Index specifying network interface.
interface_name	Pointer to the buffer that holds the name of the network interface.
ip_address	Pointer to the destination for the IP address of the interface.
network_mask	Pointer to destination for network mask.
mtu_size	Pointer to destination for maximum transfer unit for this interface.
physical_address_msw	Pointer to destination for top 16 bits of the device MAC address.
physical_address_lsw	Pointer to destination for lower 32 bits of the device MAC address.

Return Values

NX_SUCCESS	(0x00)	Interface information has been obtained.
NX_PTR_ERROR	(0x07)	Invalid pointer input.

NX_INVALID_INTERFACE (0x4C)	Invalid IP pointer.
NX_CALLER_ERROR (0x11)	Service is not called from system initialization or thread context.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```

/* Retrieve interface parameters for the specified interface (index
   1 in IP instance list of interfaces). */
#define INTERFACE_INDEX 1
status = nx_ip_interface_info_get(ip_ptr, INTERFACE_INDEX,
                                   &name_ptr, &ip_address,
                                   &network_mask,
                                   &mtu_size,
                                   &physical_address_msw,
                                   &physical_address_lsw);

/* If status is NX_SUCCESS the interface information is
   successfully retrieved. */

```

nx_ip_interface_status_check

Check status of an IP instance

Prototype

```
UINT nx_ip_interface_status_check(NX_IP *ip_ptr,
                                  UINT interface_index,
                                  ULONG needed_status,
                                  ULONG *actual_status,
                                  ULONG wait_option);
```

Description

This service checks and optionally waits for the specified status of the network interface of a previously created IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.
interface_index	Interface index number
needed_status	IP status requested, defined in bit-map form as follows: NX_IP_INITIALIZE_DONE (0x0001) NX_IP_ADDRESS_RESOLVED (0x0002) NX_IP_LINK_ENABLED (0x0004) NX_IP_ARP_ENABLED (0x0008) NX_IP_UDP_ENABLED (0x0010) NX_IP_TCP_ENABLED (0x0020) NX_IP_IGMP_ENABLED (0x0040) NX_IP_RARP_COMPLETE (0x0080) NX_IP_INTERFACE_LINK_ENABLED (0x0100)
actual_status	Pointer to destination of actual bits set.
wait_option	Defines how the service behaves if the requested status bits are not available. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFF)

Return Values

NX_SUCCESS	(0x00)	Successful IP status check.
NX_NOT_SUCCESSFUL	(0x43)	Status request was not satisfied within the timeout specified.
NX_PTR_ERROR	(0x07)	IP pointer is or has become invalid, or actual status pointer is invalid.
NX_OPTION_ERROR	(0x0a)	Invalid needed status option.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_INVALID_INTERFACE	(0x4C)	Interface_index is out of range. or the interface is not valid.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Wait 10 ticks for the link up status on the previously created IP
   instance. */
status = nx_ip_interface_status_check(&ip_0, 1, NX_IP_LINK_ENABLED,
                                     &actual_status, 10);

/* If status is NX_SUCCESS, the secondary link for the specified IP
   instance is up. */
```

See Also

`nx_ip_interface_address_get`, `nx_ip_interface_address_set`,
`nx_ip_interface_attach`, `nx_ip_interface_info_get`,
`nx_ip_link_status_change_notify_set`

nx_ip_link_status_change_notify_set

Set the link status change notify callback function

Prototype

```
UINT nx_ip_link_status_change_notify_set(NX_IP *ip_ptr,
                                         VOID(*link_status_change_notify)(NX_IP *ip_ptr,
                                         UINT interface_index, UINT link_up))
```

Description

This service configures the link status change notify callback function. The user-supplied *link_status_change_notify* routine is invoked when either the primary or secondary interface status is changed (such as IP address is changed.) If *link_status_change_notify* is NULL, the link status change notify callback feature is disabled.

Parameters

ip_ptr	IP control block pointer
link_status_change_notify	User-supplied callback function to be called upon a change to the physical interface.

Return Values

NX_SUCCESS	(0x00)	Successful set
NX_PTR_ERROR	(0x07)	Invalid IP control block pointer or new physical address pointer
NX_CALLER_ERROR	(0x11)	Service is not called from system initialization or thread context.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Configure a callback function to be used when the physical
   interface status is changed. */
status = nx_ip_link_status_change_notify_set(&ip_0,
                                              my_change_cb);

/* If status == NX_SUCCESS, the link status change notify function
   is set. */
```

See Also

`nx_ip_interface_address_get`, `nx_ip_interface_address_set`,
`nx_ip_interface_attach`, `nx_ip_interface_info_get`,
`nx_ip_interface_status_check`

Example

```
/* Disable raw packet sending/receiving for this IP instance. */  
status = nx_ip_raw_packet_disable(&ip_0);  
  
/* If status is NX_SUCCESS, raw IP packet sending/receiving has  
   been disabled for the previously created IP instance. */
```

See Also

`nx_ip_raw_packet_enable`, `nx_ip_raw_packet_receive`,
`nx_ip_raw_packet_send`, `nx_ip_raw_packet_interface_send`

Example

```
/* Enable raw packet sending/receiving for this IP instance. */  
status = nx_ip_raw_packet_enable(&ip_0);  
  
/* If status is NX_SUCCESS, raw IP packet sending/receiving has  
   been enabled for the previously created IP instance. */
```

See Also

`nx_ip_raw_packet_disable`, `nx_ip_raw_packet_receive`,
`nx_ip_raw_packet_send`, `nx_ip_raw_packet_interface_send`

nx_ip_raw_packet_interface_send

Send raw IP packet through specified network interface

Prototype

```
UINT nx_ip_raw_packet_interface_send(NX_IP *ip_ptr,
                                     NX_PACKET *packet_ptr,
                                     ULONG destination_ip,
                                     UINT address_index,
                                     ULONG type_of_service);
```

Description

This service sends a raw IP packet to the destination IP address using the specified local IP address as the source address, and through the associated network interface. Note that this routine returns immediately, and it is, therefore, not known if the IP packet has actually been sent. The network driver will be responsible for releasing the packet when the transmission is complete. This service differs from other services in that there is no way of knowing if the packet was actually sent. It could get lost on the Internet.

Note that raw IP processing must be enabled.

*This service is similar to **nx_ip_raw_packet_send**, except that this service allows an application to send raw IP packet from a specified physical interfaces.*

Parameters

ip_ptr	Pointer to previously created IP task.
packet_ptr	Pointer to packet to transmit.
destination_ip	IP address to send packet.
address_index	Index of the address of the interface to send packet out on.
type_of_service	Type of service for packet.

Return Values

NX_SUCCESS	(0x00)	Packet successfully transmitted.
NX_IP_ADDRESS_ERROR	(0x21)	No suitable outgoing interface available.
NX_NOT_ENABLED	(0x14)	Raw IP packet processing not enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid pointer input.
NX_OPTION_ERROR	(0x0A)	Invalid type of service specified.
NX_OVERFLOW	(0x03)	Invalid packet prepend pointer.
NX_UNDERFLOW	(0x02)	Invalid packet prepend pointer.
NX_INVALID_INTERFACE	(0x4C)	Invalid interface index specified.

Allowed From

Threads

Preemption Possible

No

Example

```
#define ADDRESS_IDNEX 1
/* Send packet out on interface 1 with normal type of service. */
status = nx_ip_raw_packet_interface_send(ip_ptr, packet_ptr,
                                          destination_ip,
                                          ADDRESS_INDEX,
                                          NX_IP_NORMAL);

/* If status is NX_SUCCESS the packet was successfully
   transmitted. */
```

See Also

`nx_ip_raw_packet_disable`, `nx_ip_raw_packet_enable`,
`nx_ip_raw_packet_receive`, `nx_ip_raw_packet_send`

nx_ip_raw_packet_receive

Receive raw IP packet

Prototype

```
UINT nx_ip_raw_packet_receive(NX_IP *ip_ptr,
                              NX_PACKET **packet_ptr,
                              ULONG wait_option);
```

Description

This service receives a raw IP packet from the specified IP instance. If there are IP packets on the raw packet receive queue, the first (oldest) packet is returned to the caller. Otherwise, if no packets are available, the caller may suspend as specified by the wait option.

 If *NX_SUCCESS*, is returned, the application is responsible for releasing the received packet when it is no longer needed.

Parameters

ip_ptr	Pointer to previously created IP instance.
packet_ptr	Pointer to pointer to place the received raw IP packet in.
wait_option	Defines how the service behaves if there are no raw IP packets available. The wait options are defined as follows: <div><div><div>NX_NO_WAIT</div><div>NX_WAIT_FOREVER</div><div>timeout value in ticks</div></div><div><div>(0x00000000)</div><div>(0xFFFFFFFF)</div><div>(0x00000001 through 0xFFFFFFFFE)</div></div></div>

Return Values

NX_SUCCESS	(0x00)	Successful IP raw packet receive.
NX_NO_PACKET	(0x01)	No packet was available.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .

NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_PTR_ERROR	(0x07)	Invalid IP or return packet pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service

Allowed From

Threads

Preemption Possible

No

Example

```
/* Receive a raw IP packet for this IP instance, wait for a maximum
   of 4 timer ticks. */
status = nx_ip_raw_packet_receive(&ip_0, &packet_ptr, 4);

/* If status is NX_SUCCESS, the raw IP packet pointer is in the
   variable packet_ptr. */
```

See Also

`nx_ip_raw_packet_disable`, `nx_ip_raw_packet_enable`,
`nx_ip_raw_packet_send`, `nx_ip_raw_packet_interface_send`

nx_ip_raw_packet_send

Send raw IP packet

Prototype

```
UINT nx_ip_raw_packet_send(NX_IP *ip_ptr,
                           NX_PACKET *packet_ptr,
                           ULONG destination_ip,
                           ULONG type_of_service);
```

Description

This service sends a raw IP packet to the destination IP address. Note that this routine returns immediately, and it is therefore not known whether the IP packet has actually been sent. The network driver will be responsible for releasing the packet when the transmission is complete.

For a multihome system, NetX uses the destination IP address to find an appropriate network interface and uses the IP address of the interface as the source address. If the destination IP address is broadcast or multicast, the first valid interface is used. Applications use the **nx_ip_raw_packet_interface_send** in this case.

 *Unless an error is returned, the application should not release the packet after this call. Doing so will cause unpredictable results because the network driver will release the packet after transmission.*

Parameters

ip_ptr	Pointer to previously created IP instance.
packet_ptr	Pointer to the raw IP packet to send.
destination_ip	Destination IP address, which can be a specific host IP address, a network broadcast, an internal loop-back, or a multicast address.
type_of_service	Defines the type of service for the transmission, legal values are as follows: <div><div>NX_IP_NORMAL0x00000000</div><div>NX_IP_MIN_DELAY0x00100000</div><div>NX_IP_MAX_DATA0x00080000</div><div>NX_IP_MAX_RELIABLE0x00040000</div><div>NX_IP_MIN_COST0x00020000</div></div>

Return Values

NX_SUCCESS	(0x00)	Successful IP raw packet send initiated.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_NOT_ENABLED	(0x14)	Raw IP feature is not enabled.
NX_OPTION_ERROR	(0x0A)	Invalid type of service.
NX_UNDERFLOW	(0x02)	Not enough room to prepend an IP header on the packet.
NX_OVERFLOW	(0x03)	Packet append pointer is invalid.
NX_PTR_ERROR	(0x07)	Invalid IP or packet pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Send a raw IP packet to IP address 1.2.3.5. */
status = nx_ip_raw_packet_send(&ip_0, packet_ptr,
                               IP_ADDRESS(1,2,3,5),
                               NX_IP_NORMAL);

/* If status is NX_SUCCESS, the raw IP packet pointed to by
   packet_ptr has been sent. */
```

See Also

`nx_ip_raw_packet_receive`, `nx_ip_raw_packet_send`,
`nx_ip_raw_packet_interface_send`

nx_ip_static_route_add

Add static route to the routing table

Prototype

```
UINT nx_ip_static_route_add(NX_IP *ip_ptr,
                             ULONG network_address,
                             ULONG net_mask,
                             ULONG next_hop);
```

Description

This service adds an entry to the static routing table. Note that the *next_hop* address must be directly accessible from one of the local network devices.

 *Note that ip_ptr must point to a valid NetX IP structure and the NetX library must be built with NX_ENABLE_IP_STATIC_ROUTING defined to use this service. By default NetX is built without NX_ENABLE_IP_STATIC_ROUTING defined.*

Parameters

ip_ptr	Pointer to previously created IP instance.
network_address	Target network address, in host byte order
net_mask	Target network mask, in host byte order
next_hop	Next hop address for the target network, in host byte order

Return Values

NX_SUCCESS	(0x00)	Entry is added to the static routing table.
NX_OVERFLOW	(0x03)	Static routing table is full.
NX_NOT_SUPPORTED	(0x4B)	This feature is not compiled in.
NX_IP_ADDRESS_ERROR	(0x21)	Next hop is not directly accessible via local interfaces.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid ip_ptr pointer.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Specify the next hop for the 192.168.10.0 through the gateway
   192.168.1.1. */
status = nx_ip_static_route_add(ip_ptr, IP_ADDRESS(192,168,10,0),
                                0xFFFFFFFF0UL,
                                IP_ADDRESS(192,168,1,1));

/* If status is NX_SUCCESS the route was successfully added to the
   static routing table. */
```

See Also

`nx_ip_gateway_address_set`, `nx_ip_info_get`, `nx_ip_static_route_delete`

nx_ip_static_route_delete

Delete static route from routing table

Prototype

```
UINT nx_ip_static_route_delete(NX_IP *ip_ptr,
                               ULONG network_address,
                               ULONG net_mask);
```

Description

This service deletes an entry from the static routing table.

 *Note that ip_ptr must point to a valid NetX IP structure and the NetX library must be built with NX_ENABLE_IP_STATIC_ROUTING defined to use this service. By default NetX is built without NX_ENABLE_IP_STATIC_ROUTING defined.*

Parameters

ip_ptr	Pointer to previously created IP instance.
network_address	Target network address, in host byte order.
net_mask	Target network mask, in host byte order.

Return Values

NX_SUCCESS	(0x00)	Successful deletion from the static routing table.
NX_NOT_SUCCESSFUL	(0x43)	Entry cannot be found in the routing table.
NX_NOT_SUPPORTED	(0x4B)	This feature is not compiled in.
NX_PTR_ERROR	(0x07)	Invalid ip_ptr pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Remove the static route for 192.168.10.0 from the routing
   table.*/
status = nx_ip_static_route_delete(ip_ptr,
                                   IP_ADDRESS(192,168,10,0),
                                   0xFFFFFFFF00UL);

/* If status is NX_SUCCESS the route was successfully removed from
   the static routing table. */
```

See Also

`nx_ip_gateway_address_set`, `nx_ip_info_get`, `nx_ip_static_route_add`

nx_ip_status_check

Check status of an IP instance

Prototype

```
UINT nx_ip_status_check(NX_IP *ip_ptr,
                        ULONG needed_status,
                        ULONG *actual_status,
                        ULONG wait_option);
```

Description

This service checks and optionally waits for the specified status of the primary network interface of a previously created IP instance. To obtain status on secondary interfaces, applications shall use the service *nx_ip_interface_status_check*.

Parameters

ip_ptr	Pointer to previously created IP instance.
needed_status	IP status requested, defined in bit-map form as follows: <div><div>NX_IP_INITIALIZE_DONE</div><div>(0x0001)</div><div>NX_IP_ADDRESS_RESOLVED</div><div>(0x0002)</div><div>NX_IP_LINK_ENABLED</div><div>(0x0004)</div><div>NX_IP_ARP_ENABLED</div><div>(0x0008)</div><div>NX_IP_UDP_ENABLED</div><div>(0x0010)</div><div>NX_IP_TCP_ENABLED</div><div>(0x0020)</div><div>NX_IP_IGMP_ENABLED</div><div>(0x0040)</div><div>NX_IP_RARP_COMPLETE</div><div>(0x0080)</div><div>NX_IP_INTERFACE_LINK_ENABLED</div><div>(0x0100)</div></div>
actual_status	Pointer to destination of actual bits set.
wait_option	Defines how the service behaves if the requested status bits are not available. The wait options are defined as follows: <div><div>NX_NO_WAIT</div><div>(0x00000000)</div><div>NX_WAIT_FOREVER</div><div>(0xFFFFFFFF)</div><div>timeout value in ticks</div><div>(0x00000001 through 0xFFFFFFFF)</div></div>

Return Values

NX_SUCCESS	(0x00)	Successful IP status check.
NX_NOT_SUCCESSFUL	(0x43)	Status request was not satisfied within the timeout specified.
NX_PTR_ERROR	(0x07)	IP pointer is or has become invalid, or actual status pointer is invalid.
NX_OPTION_ERROR	(0x0a)	Invalid needed status option.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Wait 10 ticks for the link up status on the previously created IP
   instance. */
status = nx_ip_status_check(&ip_0, NX_IP_LINK_ENABLED,
                           &actual_status, 10);

/* If status is NX_SUCCESS, the link for the specified IP instance
   is up. */
```

nx_packet_allocate

Allocate packet from specified pool

Prototype

```
UINT nx_packet_allocate(NX_PACKET_POOL *pool_ptr,
                        NX_PACKET **packet_ptr,
                        ULONG packet_type,
                        ULONG wait_option);
```

Description

This service allocates a packet from the specified pool and adjusts the prepend pointer in the packet according to the type of packet specified. If no packet is available, the service suspends according to the supplied wait option.

Parameters

pool_ptr	Pointer to previously created packet pool.						
packet_ptr	Pointer to the pointer of the allocated packet pointer.						
packet_type	Defines the type of packet requested. See “Packet Pools” on page 49 in Chapter 3 for a list of supported packet types.						
wait_option	Defines the wait time in ticks if there are no packets available in the packet pool. The wait options are defined as follows: <table data-bbox="643 1052 1150 1170"> <tr> <td>NX_NO_WAIT</td><td>(0x00000000)</td></tr> <tr> <td>NX_WAIT_FOREVER</td><td>(0xFFFFFFFF)</td></tr> <tr> <td>timeout value in ticks</td><td>(0x00000001 through 0xFFFFFFFFE)</td></tr> </table>	NX_NO_WAIT	(0x00000000)	NX_WAIT_FOREVER	(0xFFFFFFFF)	timeout value in ticks	(0x00000001 through 0xFFFFFFFFE)
NX_NO_WAIT	(0x00000000)						
NX_WAIT_FOREVER	(0xFFFFFFFF)						
timeout value in ticks	(0x00000001 through 0xFFFFFFFFE)						

Return Values

NX_SUCCESS	(0x00)	Successful packet allocate.
NX_NO_PACKET	(0x01)	No packet available.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_INVALID_PARAMETERS	(0x4D)	Packet size cannot support protocol.
NX_OPTION_ERROR	(0x0A)	Invalid packet type.
NX_PTR_ERROR	(0x07)	Invalid pool or packet return pointer.
NX_CALLER_ERROR	(0x11)	Invalid wait option from non-thread.

Allowed From

Initialization, threads, timers, and ISRs (application network drivers). Wait option must be *NX_NO_WAIT* when used in ISR or in timer context.

Preemption Possible

No

Example

```
/* Allocate a new UDP packet from the previously created packet pool
   and suspend for a maximum of 5 timer ticks if the pool is
   empty. */
status = nx_packet_allocate(&pool_0, &packet_ptr,
                           NX_UDP_PACKET, 5);

/* If status is NX_SUCCESS, the newly allocated packet pointer is
   found in the variable packet_ptr. */
```

See Also

`nx_packet_pool_info_get`, `nx_packet_release`,
`nx_packet_transmit_release`

nx_packet_copy

Copy packet

Prototype

```
UINT nx_packet_copy(NX_PACKET *packet_ptr,
                    NX_PACKET **new_packet_ptr,
                    NX_PACKET_POOL *pool_ptr,
                    ULONG wait_option);
```

Description

This service copies the information in the supplied packet to one or more new packets that are allocated from the supplied packet pool. If successful, the pointer to the new packet is returned in destination pointed to by **new_packet_ptr**.

Parameters

packet_ptr	Pointer to the source packet.
new_packet_ptr	Pointer to the destination of where to return the pointer to the new copy of the packet.
pool_ptr	Pointer to the previously created packet pool that is used to allocate one or more packets for the copy.
wait_option	Defines how the service waits if there are no packets available. The wait options are defined as follows: <div>NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)</div>

Return Values

NX_SUCCESS	(0x00)	Successful packet copy.
NX_NO_PACKET	(0x01)	Packet not available for copy.
NX_INVALID_PACKET	(0x12)	Empty source packet or copy failed.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to tx_thread_wait_abort.

NX_INVALID_PARAMETERS	(0x4D)	Packet size cannot support protocol.
NX_PTR_ERROR	(0x07)	Invalid pool, packet, or destination pointer.
NX_UNDERFLOW	(0x02)	Invalid packet prepend pointer.
NX_OVERFLOW	(0x03)	Invalid packet append pointer.
NX_CALLER_ERROR	(0x11)	A wait option was specified in initialization or in an ISR.

Allowed From

Initialization, threads, timers, and ISRs

Preemption Possible

No

Example

```
NX_PACKET *new_copy_ptr;

/* Copy packet pointed to by "old_packet_ptr" using packets from
   previously created packet pool_0. */
status = nx_packet_copy(old_packet, &new_copy_ptr, &pool_0, 20);

/* If status is NX_SUCCESS, new_copy_ptr points to the packet copy. */
```

See Also

nx_packet_allocate, nx_packet_data_append,

 nx_packet_transmit_release

nx_packet_data_append

Append data to end of packet

Prototype

```
UINT nx_packet_data_append(NX_PACKET *packet_ptr,
                           VOID *data_start, ULONG data_size,
                           NX_PACKET_POOL *pool_ptr,
                           ULONG wait_option);
```

Description

This service appends data to the end of the specified packet. The supplied data area is copied into the packet. If there is not enough memory available, and the chained packet feature is enabled, one or more packets will be allocated to satisfy the request. If the chained packet feature is not enabled, *NX_SIZE_ERROR* is returned.

Parameters

packet_ptr	Packet pointer.
data_start	Pointer to the start of the user's data area to append to the packet.
data_size	Size of user's data area.
pool_ptr	Pointer to packet pool from which to allocate another packet if there is not enough room in the current packet.
wait_option	Defines how the service behaves if there are no packets available. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful packet append.
NX_NO_PACKET	(0x01)	No packet available.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .

NX_INVALID_PARAMETERS

	(0x4D)	Packet size cannot support protocol.
NX_UNDERFLOW	(0x02)	Prepend pointer is less than payload start.
NX_OVERFLOW	(0x03)	Append pointer is greater than payload end.
NX_PTR_ERROR	(0x07)	Invalid pool, packet, or data Pointer.
NX_SIZE_ERROR	(0x09)	Invalid data size.
NX_CALLER_ERROR	(0x11)	Invalid wait option from non-thread.

Allowed From

Initialization, threads, timers, and ISRs (application network drivers)

Preemption Possible

No

Example

```
/* Append "abcd" to the specified packet. */
status = nx_packet_data_append(packet_ptr, "abcd", 4, &pool_0, 5);

/* If status is NX_SUCCESS, the additional four bytes "abcd" have
   been appended to the packet. */
```

`nx_packet_transmit_release`

nx_packet_data_extract_offset

Extract data from packet via an offset

Prototype

```
UINT nx_packet_data_extract_offset(NX_PACKET *packet_ptr,
                                   ULONG offset,
                                   VOID *buffer_start,
                                   ULONG buffer_length,
                                   ULONG *bytes_copied);
```

Description

This service copies data from a NetX packet (or packet chain) starting at the specified offset from the packet prepend pointer of the specified size in bytes into the specified buffer. The number of bytes actually copied is returned in *bytes_copied*. This service does not remove data from the packet, nor does it adjust the prepend pointer or other internal state information.

Parameters

packet_ptr	Pointer to packet to extract
offset	Offset from the current prepend pointer.
buffer_start	Pointer to start of save buffer
buffer_length	Number of bytes to copy
bytes_copied	Number of bytes actually copied

Return Values

NX_SUCCESS	(0x00)	Successful packet copy
NX_PACKET_OFFSET_ERROR	(0x53)	Invalid offset value was supplied
NX_PTR_ERROR	(0x07)	Invalid packet pointer or buffer pointer

Allowed From

Initialization, threads, timers, and ISRs

Preemption Possible

No

Example

```
/* Extract 10 bytes from the start of the received packet buffer
   into the specified memory area. */
status = nx_packet_data_extract_offset(my_packet, 0, &data[0], 10,
                                       &bytes_copied) ;

/* If status is NX_SUCCESS, 10 bytes were successfully copied into
   the data buffer. */
```

See Also

`nx_packet_allocate`, `nx_packet_copy`, `nx_packet_data_append`,
`nx_packet_data_retrieve`, `nx_packet_length_get`, `nx_packet_pool_create`,
`nx_packet_pool_delete`, `nx_packet_pool_info_get`, `nx_packet_release`,
`nx_packet_transmit_release`

nx_packet_data_retrieve

Retrieve data from packet

Prototype

```
UINT nx_packet_data_retrieve(NX_PACKET *packet_ptr,
                             VOID *buffer_start,
                             ULONG *bytes_copied);
```

Description

This service copies data from the supplied packet into the supplied buffer. The actual number of bytes copied is returned in the destination pointed to by **bytes_copied**.

Note that this service does not change internal state of the packet. The data being retrieved is still available in the packet.

The destination buffer must be large enough to hold the packet's contents. If not, memory will be corrupted causing unpredictable results.

Parameters

packet_ptr	Pointer to the source packet.
buffer_start	Pointer to the start of the buffer area.
bytes_copied	Pointer to the destination for the number of bytes copied.

Return Values

NX_SUCCESS	(0x00)	Successful packet data retrieve.
NX_INVALID_PACKET	(0x12)	Invalid packet.
NX_PTR_ERROR	(0x07)	Invalid packet, buffer start, or bytes copied pointer.

Allowed From

Initialization, threads, timers, and ISRs

Preemption Possible

No

Example

```
UCHAR          buffer[512];
ULONG          bytes_copied;

/* Retrieve data from packet pointed to by "packet_ptr". */
status = nx_packet_data_retrieve(packet_ptr, buffer, &bytes_copied);

/* If status is NX_SUCCESS, buffer contains the contents of the
   packet, the size of which is contained in "bytes_copied." */
```

`nx_packet_pool_info_get`, `nx_packet_release`,
`nx_packet_transmit_release`

nx_packet_length_get

Get length of packet data

Prototype

```
UINT nx_packet_length_get(NX_PACKET *packet_ptr, ULONG *length);
```

Description

This service gets the length of the data in the specified packet.

Parameters

packet_ptr	Pointer to the packet.
length	Destination for the packet length.

Return Values

NX_SUCCESS	(0x00)	Successful packet length get.
NX_PTR_ERROR	(0x07)	Invalid packet pointer.

Allowed From

Initialization, threads, timers, and ISRs

Preemption Possible

No

Example

```
/* Get the length of the data in "my_packet." */  
status = nx_packet_length_get(my_packet, &my_length);  
  
/* If status is NX_SUCCESS, data length is in "my_length". */
```

`nx_packet_pool_create`, `nx_packet_pool_delete`,
`nx_packet_pool_info_get`, `nx_packet_release`,
`nx_packet_transmit_release`

nx_packet_pool_create

Create packet pool in specified memory area

Prototype

```
UINT nx_packet_pool_create(NX_PACKET_POOL *pool_ptr,
                           CHAR *name,
                           ULONG payload_size,
                           VOID *memory_ptr,
                           ULONG memory_size);
```

Description

This service creates a packet pool of the specified packet size in the memory area supplied by the user.

Parameters

pool_ptr	Pointer to packet pool control block.
name	Pointer to application's name for the packet pool.
payload_size	Number of bytes in each packet in the pool. This value must be at least 40 bytes and must also be evenly divisible by 4.
memory_ptr	Pointer to the memory area to place the packet pool in. The pointer should be aligned on an ULONG boundary.
memory_size	Size of the pool memory area.

Return Values

NX_SUCCESS	(0x00)	Successful packet pool create.
NX_PTR_ERROR	(0x07)	Invalid pool or memory pointer.
NX_SIZE_ERROR	(0x09)	Invalid block or memory size.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Create a packet pool of 32000 bytes starting at physical
   address 0x10000000. */
status = nx_packet_pool_create(&pool_0, "Default Pool", 128,
                               (void *) 0x10000000, 32000);

/* If status is NX_SUCCESS, the packet pool has been successfully
   created. */
```

`nx_packet_length_get`, `nx_packet_pool_delete`, `nx_packet_pool_info_get`,
`nx_packet_release`, `nx_packet_transmit_release`

nx_packet_pool_delete

Delete previously created packet pool

Prototype

```
UINT nx_packet_pool_delete(NX_PACKET_POOL *pool_ptr);
```

Description

This service deletes a previously created packet pool. NetX checks for any threads currently suspended on packets in the packet pool and clears the suspension.

Parameters

pool_ptr Packet pool control block pointer.

Return Values

NX_SUCCESS	(0x00)	Successful packet pool delete.
NX_PTR_ERROR	(0x07)	Invalid pool pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

Yes

Example

```
/* Delete a previously created packet pool. */
status = nx_packet_pool_delete(&pool_0);

/* If status is NX_SUCCESS, the packet pool has been successfully
   deleted. */
```

See Also

`nx_packet_data_extract_offset`, `nx_packet_data_retrieve`,
`nx_packet_length_get`, `nx_packet_pool_create`,
`nx_packet_pool_info_get`, `nx_packet_release`,
`nx_packet_transmit_release`

nx_packet_pool_info_get

Retrieve information about a packet pool

Prototype

```
UINT nx_packet_pool_info_get(NX_PACKET_POOL *pool_ptr,
                             ULONG *total_packets,
                             ULONG *free_packets,
                             ULONG *empty_pool_requests,
                             ULONG *empty_pool_suspensions,
                             ULONG *invalid_packet_releases);
```

Description

This service retrieves information about the specified packet pool.

If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

pool_ptr	Pointer to previously created packet pool.
total_packets	Pointer to destination for the total number of packets in the pool.
free_packets	Pointer to destination for the total number of currently free packets.
empty_pool_requests	Pointer to destination of the total number of allocation requests when the pool was empty.
empty_pool_suspensions	Pointer to destination of the total number of empty pool suspensions.
invalid_packet_releases	Pointer to destination of the total number of invalid packet releases.

Return Values

NX_SUCCESS	(0x00)	Successful packet pool information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads, and timers

Preemption Possible

No

Example

```
/* Retrieve packet pool information. */
status = nx_packet_pool_info_get(&pool_0,
                                &total_packets,
                                &free_packets,
                                &empty_pool_requests,
                                &empty_pool_suspensions,
                                &invalid_packet_releases);

/* If status is NX_SUCCESS, packet pool information was
   retrieved. */
```

`nx_packet_release`, `nx_packet_transmit_release`

nx_packet_release

Release previously allocated packet

Prototype

```
UINT nx_packet_release(NX_PACKET *packet_ptr);
```

Description

This service releases a packet, including any additional packets chained to the specified packet. If another thread is blocked on packet allocation, it is given the packet and resumed.

The application must prevent releasing a packet more than once, because doing so will cause unpredictable results.

Parameters

packet_ptr Packet pointer.

Return Values

NX_SUCCESS	(0x00)	Successful packet release.
NX_PTR_ERROR	(0x07)	Invalid packet pointer.
NX_UNDERFLOW	(0x02)	Prepend pointer is less than payload start.
NX_OVERFLOW	(0x03)	Append pointer is greater than payload end.

Allowed From

Initialization, threads, timers, and ISRs (application network drivers)

Preemption Possible

Yes

Example

```
/* Release a previously allocated packet. */
status = nx_packet_release(packet_ptr);

/* If status is NX_SUCCESS, the packet has been returned to the
   packet pool it was allocated from. */
```

See Also

`nx_packet_data_extract_offset`, `nx_packet_data_retrieve`,
`nx_packet_length_get`, `nx_packet_pool_create`, `nx_packet_pool_delete`,
`nx_packet_pool_info_get`, `nx_packet_transmit_release`

nx_packet_transmit_release

Release a transmitted packet

Prototype

```
UINT nx_packet_transmit_release(NX_PACKET *packet_ptr);
```

Description

For non-TCP packets, this service releases a transmitted packet, including any additional packets chained to the specified packet. If another thread is blocked on packet allocation, it is given the packet and resumed. For a transmitted TCP packet, the packet is marked as being transmitted but not released till the packet is acknowledged. This service is typically called from the application's network driver after a packet is transmitted.

The network driver should remove the physical media header and adjust the length of the packet before calling this service.

Parameters

packet_ptr	Packet pointer.
------------	-----------------

Return Values

NX_SUCCESS	(0x00)	Successful transmit packet release.
NX_PTR_ERROR	(0x07)	Invalid packet pointer.
NX_UNDERFLOW	(0x02)	Prepend pointer is less than payload start.
NX_OVERFLOW	(0x03)	Append pointer is greater than payload end.

Allowed From

Initialization, threads, timers, Application network drivers (including ISRs)

Preemption Possible

Yes

Example

```
/* Release a previously allocated packet that was just transmitted
   from the application network driver. */
status = nx_packet_transmit_release(packet_ptr);

/* If status is NX_SUCCESS, the transmitted packet has been
   returned to the packet pool it was allocated from. */
```

See Also

`nx_packet_data_extract_offset`, `nx_packet_data_retrieve`,
`nx_packet_length_get`, `nx_packet_pool_create`, `nx_packet_pool_delete`,
`nx_packet_pool_info_get`, `nx_packet_release`

Example

```
/* Disable RARP on the previously created IP instance. */
status = nx_rarp_disable(&ip_0);

/* If status is NX_SUCCESS, RARP is disabled. */
```

See Also

`nx_rarp_enable`, `nx_rarp_info_get`

Example

```
/* Enable RARP on the previously created IP instance. */
status = nx_rarp_enable(&ip_0);

/* If status is NX_SUCCESS, RARP is enabled and is attempting to
   resolve this IP instance's address by querying the network. */
```

See Also

`nx_rarp_disable`, `nx_rarp_info_get`

nx_rarp_info_get

Retrieve information about RARP activities

Prototype

```
UINT nx_rarp_info_get(NX_IP *ip_ptr,
                     ULONG *rarp_requests_sent,
                     ULONG *rarp_responses_received,
                     ULONG *rarp_invalid_messages);
```

Description

This service retrieves information about RARP activities for the specified IP instance.

i If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

ip_ptr	Pointer to previously created IP instance.
rarp_requests_sent	Pointer to destination for the total number of RARP requests sent.
rarp_responses_received	Pointer to destination for the total number of RARP responses received.
rarp_invalid_messages	Pointer to destination of the total number of invalid messages.

Return Values

NX_SUCCESS	(0x00)	Successful RARP information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Retrieve RARP information from previously created IP
   Instance 0. */
status = nx_rarp_info_get(&ip_0,
                          &rarp_requests_sent,
                          &rarp_responses_received,
                          &rarp_invalid_messages);

/* If status is NX_SUCCESS, RARP information was retrieved. */
```

See Also

`nx_rarp_disable`, `nx_rarp_enable`

nx_system_initialize

Initialize NetX System

Prototype

```
VOID nx_system_initialize(VOID);
```

Description

This service initializes the basic NetX system resources in preparation for use. It should be called by the application during initialization and before any other NetX call are made.

Parameters

None

Return Values

None

Allowed From

Initialization, threads, timers, ISRs

Preemption Possible

No

Example

```
/* Initialize NetX for operation. */
nx_system_initialize();

/* At this point, NetX is ready for IP creation and all subsequent
network operations. */
```

See Also

`nx_ip_forwarding_enable`, `nx_ip_fragment_disable`,
`nx_ip_fragment_enable`, `nx_ip_info_get`, `nx_ip_status_check`

nx_tcp_client_socket_bind

Bind client TCP socket to TCP port

Prototype

```
UINT nx_tcp_client_socket_bind(NX_TCP_SOCKET *socket_ptr,
                               UINT port,
                               ULONG wait_option);
```

Description

This service binds the previously created TCP client socket to the specified TCP port. Valid TCP sockets range from 0 through 0xFFFF. If the specified TCP port is unavailable, the service suspends according to the supplied wait option.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
port	Port number to bind (1 through 0xFFFF). If port number is NX_ANY_PORT (0x0000), the IP instance will search for the next free port and use that for the binding.
wait_option	Defines how the service behaves if the port is already bound to another socket. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful socket bind.
NX_ALREADY_BOUND	(0x22)	This socket is already bound to another TCP port.
NX_PORT_UNAVAILABLE	(0x23)	Port is already bound to a different socket.
NX_NO_FREE_PORTS	(0x45)	No free port.

NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_INVALID_PORT	(0x46)	Invalid port.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Bind a previously created client socket to port 12 and wait for 7
   timer ticks for the bind to complete. */
status = nx_tcp_client_socket_bind(&client_socket, 12, 7);

/* If status is NX_SUCCESS, the previously created client_socket is
   bound to port 12 on the associated IP instance. */

```

 nx_tcp_socket_state_wait

nx_tcp_client_socket_connect

Connect client TCP socket

Prototype

```
UINT nx_tcp_client_socket_connect(NX_TCP_SOCKET *socket_ptr,
                                  ULONG server_ip,
                                  UINT server_port,
                                  ULONG wait_option);
```

Description

This service connects the previously created and bound TCP client socket to the specified server's port. Valid TCP server ports range from 0 through 0xFFFF. If the connection does not complete immediately, the service suspends according to the supplied wait option.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
server_ip	Server's IP address.
server_port	Server port number to connect to (1 through 0xFFFF).
wait_option	Defines how the service behaves while the connection is being established. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful socket connect.
NX_NOT_BOUND	(0x24)	Socket is not bound.
NX_NOT_CLOSED	(0x35)	Socket is not in a closed state.
NX_IN_PROGRESS	(0x37)	No wait was specified, the connection attempt is in progress.
NX_INVALID_INTERFACE	(0x4C)	Invalid interface supplied.

NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_IP_ADDRESS_ERROR	(0x21)	Invalid server IP address.
NX_INVALID_PORT	(0x46)	Invalid port.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Initiate a TCP connection from a previously created and bound
   client socket. The connection requested in this example is to
   port 12 on the server with the IP address of 1.2.3.5. This
   service will wait 300 timer ticks for the connection to take
   place before giving up. */
status = nx_tcp_client_socket_connect(&client_socket,
                                      IP_ADDRESS(1,2,3,5),
                                      12, 300);

/* If status is NX_SUCCESS, the previously created and bound
   client_socket is connected to port 12 on IP 1.2.3.5. */

```

```

nx_tcp_client_socket_port_get

Get port number bound to client TCP socket

Prototype

```
UINT nx_tcp_client_socket_port_get(NX_TCP_SOCKET *socket_ptr,
                                   UINT *port_ptr);
```

Description

This service retrieves the port number associated with the socket, which is useful to find the port allocated by NetX in situations where the NX_ANY_PORT was specified at the time the socket was bound.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
port_ptr	Pointer to destination for the return port number. Valid port numbers are (1 through 0xFFFF).

Return Values

NX_SUCCESS	(0x00)	Successful socket bind.
NX_NOT_BOUND	(0x24)	This socket is not bound to a port.
NX_PTR_ERROR	(0x07)	Invalid socket pointer or port return pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Get the port number of previously created and bound client
   socket. */
status = nx_tcp_client_socket_port_get(&client_socket, &port);

/* If status is NX_SUCCESS, the port variable contains the port this
   socket is bound to. */
```

```

nx_tcp_client_socket_unbind

Unbind TCP client socket from TCP port

Prototype

```
UINT nx_tcp_client_socket_unbind(NX_TCP_SOCKET *socket_ptr)
```

Description

This service releases the binding between the TCP client socket and a TCP port. If there are other threads waiting to bind another socket to the same port number, the first suspended thread is then bound to this port.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
------------	--

Return Values

NX_SUCCESS	(0x00)	Successful socket unbind.
NX_NOT_BOUND	(0x24)	Socket was not bound to any port.
NX_NOT_CLOSED	(0x35)	Socket has not been disconnected.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

Yes

Example

```
/* Unbind a previously created and bound client TCP socket.  
status = nx_tcp_client_socket_unbind(&client_socket);  
  
/* If status is NX_SUCCESS, the client socket is no longer  
bound. */
```

nx_tcp_free_port_find

Find next available TCP port

Prototype

```
UINT nx_tcp_free_port_find(NX_IP *ip_ptr,
                          UINT port,
                          UINT *free_port_ptr);
```

Description

This service attempts to locate a free TCP port (unbound) starting from the application supplied port. The search logic will wrap around if the search happens to reach the maximum port value of 0xFFFF. If the search is successful, the free port is returned in the variable pointed to by *free_port_ptr*.

This service can be called from another thread and have the same port returned. To prevent this race condition, the application may wish to place this service and the actual client socket bind under the protection of a mutex.

Parameters

ip_ptr	Pointer to previously created IP instance.
port	Port number to start search at (1 through 0xFFFF).
free_port_ptr	Pointer to the destination free port return value.

Return Values

NX_SUCCESS	(0x00)	Successful free port find.
NX_NO_FREE_PORTS	(0x45)	No free ports found.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_INVALID_PORT	(0x46)	The specified port number is invalid.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Locate a free TCP port, starting at port 12, on a previously
   created IP instance. */
status = nx_tcp_free_port_find(&ip_0, 12, &free_port);

/* If status is NX_SUCCESS, "free_port" contains the next free port
   on the IP instance. */
```

nx_tcp_info_get

Retrieve information about TCP activities

Prototype

```
UINT nx_tcp_info_get(NX_IP *ip_ptr,
                    ULONG *tcp_packets_sent,
                    ULONG *tcp_bytes_sent,
                    ULONG *tcp_packets_received,
                    ULONG *tcp_bytes_received,
                    ULONG *tcp_invalid_packets,
                    ULONG *tcp_receive_packets_dropped,
                    ULONG *tcp_checksum_errors,
                    ULONG *tcp_connections,
                    ULONG *tcp_disconnections,
                    ULONG *tcp_connections_dropped,
                    ULONG *tcp_retransmit_packets);
```

Description

This service retrieves information about TCP activities for the specified IP instance.

i

If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

ip_ptr	Pointer to previously created IP instance.
tcp_packets_sent	Pointer to destination for the total number of TCP packets sent.
tcp_bytes_sent	Pointer to destination for the total number of TCP bytes sent.
tcp_packets_received	Pointer to destination of the total number of TCP packets received.
tcp_bytes_received	Pointer to destination of the total number of TCP bytes received.
tcp_invalid_packets	Pointer to destination of the total number of invalid TCP packets.
tcp_receive_packets_dropped	Pointer to destination of the total number of TCP receive packets dropped.
tcp_checksum_errors	Pointer to destination of the total number of TCP packets with checksum errors.

tcp_connections	Pointer to destination of the total number of TCP connections.
tcp_disconnections	Pointer to destination of the total number of TCP disconnections.
tcp_connections_dropped	Pointer to destination of the total number of TCP connections dropped.
tcp_retransmit_packets	Pointer to destination of the total number of TCP packets retransmitted.

Return Values

NX_SUCCESS	(0x00)	Successful TCP information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```

/* Retrieve TCP information from previously created IP Instance
   ip_0. */
status = nx_tcp_info_get(&ip_0,
                        &tcp_packets_sent,
                        &tcp_bytes_sent,
                        &tcp_packets_received,
                        &tcp_bytes_received,
                        &tcp_invalid_packets,
                        &tcp_receive_packets_dropped,

nx_tcp_server_socket_accept

Accept TCP connection

Prototype

```
UINT nx_tcp_server_socket_accept(NX_TCP_SOCKET *socket_ptr,
                                ULONG wait_option);
```

Description

This service accepts (or prepares to accept) a TCP client socket connection request for a port that was previously set up for listening. This service may be called immediately after the application calls the listen or re-listen service or after the listen callback routine is called when the client connection is actually present. If a connection cannot not be established right away, the service suspends according to the supplied wait option.

 *The application must call **nx_tcp_server_socket_unaccept** after the connection is no longer needed to remove the server socket's binding to the server port.*

 *Application callback routines are called from within the IP's helper thread.*

Parameters

socket_ptr	Pointer to the TCP server socket control block.
wait_option	Defines how the service behaves while the connection is being established. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful TCP server socket accept (passive connect).
NX_NOT_LISTEN_STATE	(0x36)	The server socket supplied is not in a listen state.

NX_IN_PROGRESS	(0x37)	No wait was specified, the connection attempt is in progress.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_PTR_ERROR	(0x07)	Socket pointer error.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

`nx_tcp_server_socket_listen`

Enable listening for client connection on TCP port

Prototype

```
UINT nx_tcp_server_socket_listen(NX_IP *ip_ptr, UINT port,
                                NX_TCP_SOCKET *socket_ptr,
                                UINT listen_queue_size,
                                VOID (*listen_callback)
                                (NX_TCP_SOCKET *socket_ptr,
                                 UINT port));
```

Description

This service enables listening for a client connection request on the specified TCP port. When a client connection request is received, the supplied server socket is bound to the specified port and the supplied listen callback function is called.

The listen callback routine's processing is completely up to the application. It may contain logic to wake up an application thread that subsequently performs an accept operation. If the application already has a thread suspended on accept processing for this socket, the listen callback routine may not be needed.

If the application wishes to handle additional client connections on the same port, the **`nx_tcp_server_socket_relisten`** must be called with an available socket (a socket in the CLOSED state) for the next connection. Until the re-listen service is called, additional client connections are queued. When the maximum queue depth is exceeded, the oldest connection request is dropped in favor of queuing the new connection request. The maximum queue depth is specified by this service.

i Application callback routines are called from the internal IP helper thread.

Parameters

<code>ip_ptr</code>	Pointer to previously created IP instance.
<code>port</code>	Port number to listen on (1 through 0xFFFF).
<code>socket_ptr</code>	Pointer to socket to use for the connection.
<code>listen_queue_size</code>	Number of client connection requests that can be queued.

listen_callback

Application function to call when the connection is received. If a NULL is specified, the listen callback feature is disabled.

Return Values

NX_SUCCESS	(0x00)	Successful TCP port listen enable.
NX_MAX_LISTEN	(0x33)	No more listen request structures are available. The constant NX_MAX_LISTEN_REQUESTS in <i>nx_api.h</i> defines how many active listen requests are possible.
NX_NOT_CLOSED	(0x35)	The supplied server socket is not in a closed state.
NX_ALREADY_BOUND	(0x22)	The supplied server socket is already bound to a port.
NX_DUPLICATE_LISTEN	(0x34)	There is already an active listen request for this port.
NX_INVALID_PORT	(0x46)	Invalid port specified.
NX_PTR_ERROR	(0x07)	Invalid IP or socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

nx_tcp_server_socket_relisten

Re-listen for client connection on TCP port

Prototype

```
UINT nx_tcp_server_socket_relisten(NX_IP *ip_ptr, UINT port,
                                   NX_TCP_SOCKET *socket_ptr);
```

Description

This service is called after a connection has been received on a port that was setup previously for listening. The main purpose of this service is to provide a new server socket for the next client connection. If a connection request is queued, the connection will be processed immediately during this service call.

i The same callback routine specified by the original listen request is also called when a connection is present for this new server socket.

Parameters

ip_ptr	Pointer to previously created IP instance.
port	Port number to re-listen on (1 through 0xFFFF).
socket_ptr	Socket to use for the next client connection.

Return Values

NX_SUCCESS	(0x00)	Successful TCP port re-listen.
NX_NOT_CLOSED	(0x35)	The supplied server socket is not in a closed state.
NX_ALREADY_BOUND	(0x22)	The supplied server socket is already bound to a port.
NX_INVALID_RELISTEN	(0x47)	There is already a valid socket pointer for this port or the port specified does not have a listen request active.
NX_CONNECTION_PENDING	(0x48)	Same as NX_SUCCESS, except there was a queued connection

request and it was processed during this call.

NX_INVALID_PORT	(0x46)	Invalid port specified.
NX_PTR_ERROR	(0x07)	Invalid IP or listen callback pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

nx_tcp_server_socket_unaccept

Remove socket association with listening port

Prototype

```
UINT nx_tcp_server_socket_unaccept(NX_TCP_SOCKET *socket_ptr);
```

Description

This service removes the association between this server socket and the specified server port. The application must call this service after a disconnection or after an unsuccessful accept call.

Parameters

socket_ptr	Pointer to previously setup server socket instance.
------------	---

Return Values

NX_SUCCESS	(0x00)	Successful server socket unaccept.
NX_NOT_LISTEN_STATE	(0x36)	Server socket is in an improper state, and is probably not disconnected.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

nx_tcp_server_socket_unlisten

Disable listening for client connection on TCP port

Prototype

```
UINT nx_tcp_server_socket_unlisten(NX_IP *ip_ptr, UINT port);
```

Description

This service disables listening for a client connection request on the specified TCP port.

Parameters

ip_ptr	Pointer to previously created IP instance.
port	Number of port to disable listening (0 through 0xFFFF).

Return Values

NX_SUCCESS	(0x00)	Successful TCP listen disable.
NX_ENTRY_NOT_FOUND	(0x16)	Listening was not enabled for the specified port.
NX_INVALID_PORT	(0x46)	Invalid port specified.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

NX_PACKET_POOL      my_pool;
NX_IP               my_ip;

nx_tcp_socket_bytes_available

Retrieves number of bytes available for retrieval

Prototype

```
UINT nx_tcp_socket_bytes_available(NX_TCP_SOCKET *socket_ptr,
                                   ULONG *bytes_available);
```

Description

This service obtains the number of bytes available for retrieval in the specified TCP socket. Note that the TCP socket must already be connected.

Parameters

socket_ptr	Pointer to previously created and connected TCP socket.
bytes_available	Pointer to destination for bytes available.

Return Values

NX_SUCCESS	(0x00)	Service executes successfully. Number of bytes available for read is returned to the caller.
NX_NOT_CONNECTED	(0x38)	Socket is not in a connected state.
NX_PTR_ERROR	(0x07)	Invalid pointers.
NX_NOT_ENABLED	(0x14)	TCP is not enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Get the bytes available for retrieval on the specified socket. */
status = nx_tcp_socket_bytes_available(&my_socket, &bytes_available);

/* Is status = NX_SUCCESS, the available bytes is returned in
   bytes_available. */
```

nx_tcp_socket_create

Create TCP client or server socket

Prototype

```
UINT nx_tcp_socket_create(NX_IP *ip_ptr, NX_TCP_SOCKET *socket_ptr,
    CHAR *name, ULONG type_of_service, ULONG fragment,
    UINT time_to_live, ULONG window_size,
    VOID (*urgent_data_callback)(NX_TCP_SOCKET *socket_ptr),
    VOID (*disconnect_callback)(NX_TCP_SOCKET *socket_ptr));
```

Description

This service creates a TCP client or server socket for the specified IP instance.

i Application callback routines are called from the thread associated with this IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.										
socket_ptr	Pointer to new TCP socket control block.										
name	Application name for this TCP socket.										
type_of_service	Defines the type of service for the transmission, legal values are as follows: <table> <tr> <td>NX_IP_NORMAL</td><td>(0x00000000)</td></tr> <tr> <td>NX_IP_MIN_DELAY</td><td>(0x00100000)</td></tr> <tr> <td>NX_IP_MAX_DATA</td><td>(0x00080000)</td></tr> <tr> <td>NX_IP_MAX_RELIABLE</td><td>(0x00040000)</td></tr> <tr> <td>NX_IP_MIN_COST</td><td>(0x00020000)</td></tr> </table>	NX_IP_NORMAL	(0x00000000)	NX_IP_MIN_DELAY	(0x00100000)	NX_IP_MAX_DATA	(0x00080000)	NX_IP_MAX_RELIABLE	(0x00040000)	NX_IP_MIN_COST	(0x00020000)
NX_IP_NORMAL	(0x00000000)										
NX_IP_MIN_DELAY	(0x00100000)										
NX_IP_MAX_DATA	(0x00080000)										
NX_IP_MAX_RELIABLE	(0x00040000)										
NX_IP_MIN_COST	(0x00020000)										
fragment	Specifies whether or not IP fragmenting is allowed. If NX_FRAGMENT_OKAY (0x0) is specified, IP fragmenting is allowed. If NX_DONT_FRAGMENT (0x4000) is specified, IP fragmenting is disabled.										
time_to_live	Specifies the 8-bit value that defines how many routers this packet can pass before being thrown away. The default value is specified by NX_IP_TIME_TO_LIVE.										

<code>window_size</code>	Defines the maximum number of bytes allowed in the receive queue for this socket
<code>urgent_data_callback</code>	Application function that is called whenever urgent data is detected in the receive stream. If this value is <code>NX_NULL</code> , urgent data is ignored.
<code>disconnect_callback</code>	Application function that is called whenever a disconnect is issued by the socket at the other end of the connection. If this value is <code>NX_NULL</code> , the disconnect callback function is disabled.

Return Values

<code>NX_SUCCESS</code>	(0x00)	Successful TCP client socket create.
<code>NX_OPTION_ERROR</code>	(0x0A)	Invalid type-of-service, fragment, invalid window size, or time-to-live option.
<code>NX_PTR_ERROR</code>	(0x07)	Invalid IP or socket pointer.
<code>NX_CALLER_ERROR</code>	(0x11)	Invalid caller of this service.
<code>NX_NOT_ENABLED</code>	(0x14)	This component has not been enabled.

Allowed From

Initialization and Threads

Preemption Possible

No

Example

```

/* Create a TCP client socket on the previously created IP instance,
   with normal delivery, IP fragmentation enabled, 0x80 time to
   live, a 200-byte receive window, no urgent callback routine, and
   the "client_disconnect" routine to handle disconnection initiated
   from the other end of the connection. */
status = nx_tcp_socket_create(&ip_0, &client_socket,
                              "Client Socket",
                              NX_IP_NORMAL, NX_FRAGMENT_OKAY,
                              0x80, 200, NX_NULL,
                              client_disconnect);

/* If status is NX_SUCCESS, the client socket is created and ready
   to be bound. */

```

nx_tcp_socket_delete

Delete TCP socket

Prototype

```
UINT nx_tcp_socket_delete(NX_TCP_SOCKET *socket_ptr);
```

Description

This service deletes a previously created TCP socket. If the socket is still bound or connected, the service returns an error code.

Parameters

socket_ptr	Previously created TCP socket
------------	-------------------------------

Return Values

NX_SUCCESS	(0x00)	Successful socket delete.
NX_NOT_CREATED	(0x27)	Socket was not created.
NX_STILL_BOUND	(0x42)	Socket is still bound.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Delete a previously created TCP client socket. */
status = nx_tcp_socket_delete(&client_socket);

/* If status is NX_SUCCESS, the client socket is deleted. */
```

nx_tcp_socket_disconnect

Disconnect client and server socket connections

Prototype

```
UINT nx_tcp_socket_disconnect(NX_TCP_SOCKET *socket_ptr,
                              ULONG wait_option);
```

Description

This service disconnects an established client or server socket connection. A disconnect of a server socket should be followed by an un-accept request, while a client socket that is disconnected is left in a state ready for another connection request. If the disconnect process cannot finish immediately, the service suspends according to the supplied wait option.

Parameters

socket_ptr	Pointer to previously connected client or server socket instance.
wait_option	Defines how the service behaves while the disconnection is in progress. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful socket disconnect.
NX_NOT_CONNECTED	(0x38)	Specified socket is not connected.
NX_IN_PROGRESS	(0x37)	Disconnect is in progress, no wait was specified.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_PTR_ERROR	(0x07)	Invalid socket pointer.

NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

Yes

Example

```
/* Disconnect from a previously established connection and wait a
   maximum of 400 timer ticks. */
status = nx_tcp_socket_disconnect(&client_socket, 400);

/* If status is NX_SUCCESS, the previously connected socket (either
   as a result of the client socket connect or the server accept) is
   disconnected. */
```

nx_tcp_socket_disconnect_complete_notify

Install TCP disconnect complete notify callback function

Prototype

```
UINT nx_tcp_socket_disconnect_complete_notify(  
    NX_TCP_SOCKET *socket_ptr,  
    VOID (*tcp_disconnect_complete_notify)  
        (NX_TCP_SOCKET *socket_ptr))
```

Description

This service registers a callback function which is invoked after a socket disconnect operation is completed. The TCP socket disconnect complete callback function is available if NetX is built with the option ***NX_ENABLE_EXTENDED_NOTIFY_SUPPORT*** defined.

Parameters

- socket_ptr

Pointer to previously connected client or server socket instance.
- tcp_disconnect_complete_notify

The callback function to be installed.

Return Values

NX_SUCCESS	(0x00)	Successfully registered the callback function.
NX_NOT_SUPPORTED	(0x4B)	The extended notify feature is not built into the NetX library
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	TCP feature is not enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Install the disconnect complete notify callback function. */  
status = nx_tcp_socket_disconnect_complete_notify(&client_socket,  
                                                  callback);
```

`nx_tcp_socket_window_update_notify_set`

nx_tcp_socket_establish_notify

Set TCP establish notify callback function

Prototype

```
UINT nx_tcp_socket_establish_notify(NX_TCP_SOCKET *socket_ptr,
    VOID (*tcp_establish_notify)(NX_TCP_SOCKET *socket_ptr))
```

Description

This service registers a callback function, which is called after a TCP socket makes a connection. The TCP socket establish callback function is available if NetX is built with the option ***NX_ENABLE_EXTENDED_NOTIFY_SUPPORT*** defined.

Parameters

socket_ptr	Pointer to previously connected client or server socket instance.
tcp_establish_notify	Callback function invoked after a TCP connection is established.

Return Values

NX_SUCCESS	(0x00)	Successfully sets the notify function.
NX_NOT_SUPPORTED	(0x4B)	The extended notify feature is not built into the NetX library
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	TCP has not been enabled by the application.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Set the function pointer "callback" as the notify function NetX
   will call when the connection is in the established state. */
status = nx_tcp_socket_establish_notify(&client_socket, callback);
```

`nx_tcp_socket_window_update_notify_set`

nx_tcp_socket_info_get

Retrieve information about TCP socket activities

Prototype

```
UINT nx_tcp_socket_info_get(NX_TCP_SOCKET *socket_ptr,  
                             ULONG *tcp_packets_sent,  
                             ULONG *tcp_bytes_sent,  
                             ULONG *tcp_packets_received,  
                             ULONG *tcp_bytes_received,  
                             ULONG *tcp_retransmit_packets,  
                             ULONG *tcp_packets_queued,  
                             ULONG *tcp_checksum_errors,  
                             ULONG *tcp_socket_state,  
                             ULONG *tcp_transmit_queue_depth,  
                             ULONG *tcp_transmit_window,  
                             ULONG *tcp_receive_window);
```

Description

This service retrieves information about TCP socket activities for the specified TCP socket instance.

i

If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
tcp_packets_sent	Pointer to destination for the total number of TCP packets sent on socket.
tcp_bytes_sent	Pointer to destination for the total number of TCP bytes sent on socket.
tcp_packets_received	Pointer to destination of the total number of TCP packets received on socket.
tcp_bytes_received	Pointer to destination of the total number of TCP bytes received on socket.
tcp_retransmit_packets	Pointer to destination of the total number of TCP packet retransmissions.
tcp_packets_queued	Pointer to destination of the total number of queued TCP packets on socket.
tcp_checksum_errors	Pointer to destination of the total number of TCP packets with checksum errors on socket.
tcp_socket_state	Pointer to destination of the socket's current state.
tcp_transmit_queue_depth	Pointer to destination of the total number of transmit packets still queued waiting for ACK.
tcp_transmit_window	Pointer to destination of the current transmit window size.
tcp_receive_window	Pointer to destination of the current receive window size.

Return Values

NX_SUCCESS	(0x00)	Successful TCP socket information retrieval.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Retrieve TCP socket information from previously created
   socket_0.*/
status = nx_tcp_socket_info_get(&socket_0,
                                &tcp_packets_sent,
                                &tcp_bytes_sent,
                                &tcp_packets_received,
                                &tcp_bytes_received,
                                &tcp_retransmit_packets,
                                &tcp_packets_queued,
                                &tcp_checksum_errors,
                                &tcp_socket_state,
                                &tcp_transmit_queue_depth,
                                &tcp_transmit_window,
                                &tcp_receive_window);

/* If status is NX_SUCCESS, TCP socket information was retrieved. */
```

nx_tcp_socket_mss_get

Get MSS of socket

Prototype

```
UINT nx_tcp_socket_mss_get(NX_TCP_SOCKET *socket_ptr, ULONG *mss);
```

Description

This service retrieves the specified socket’s local Maximum Segment Size (MSS).

Parameters

socket_ptr	Pointer to previously created socket.
mss	Destination for returning MSS.

Return Values

NX_SUCCESS	(0x00)	Successful MSS get.
NX_PTR_ERROR	(0x07)	Invalid socket or MSS destination pointer.
NX_NOT_ENABLED	(0x14)	TCP is not enabled.
NX_CALLER_ERROR	(0x11)	Caller is not a thread or initialization.

Allowed From

Initialization and threads

Preemption Possible

No

Example

```
/* Get the MSS for the socket "my_socket". */
status = nx_tcp_socket_mss_get(&my_socket, &mss_value);

/* If status is NX_SUCCESS, the "mss_value" variable contains the
   socket's current MSS value. */
```

nx_tcp_socket_mss_peer_get

Get MSS of the peer TCP socket

Prototype

```
UINT nx_tcp_socket_mss_peer_get(NX_TCP_SOCKET *socket_ptr,
                                ULONG *mss);
```

Description

This service retrieves the Maximum Segment Size (MSS) advertised by the peer socket.

Parameters

socket_ptr	Pointer to previously created and connected socket.
mss	Destination for returning the MSS.

Return Values

NX_SUCCESS	(0x00)	Successful peer MSS get.
NX_PTR_ERROR	(0x07)	Invalid socket or MSS destination pointer.
NX_NOT_ENABLED	(0x14)	TCP is not enabled.
NX_CALLER_ERROR	(0x11)	Caller is not a thread or initialization.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Get the MSS of the connected peer to the socket "my_socket". */
status = nx_tcp_socket_mss_peer_get(&my_socket, &mss_value);

/* If status is NX_SUCCESS, the "mss_value" variable contains the
   socket peer's advertised MSS value. */
```

See Also

nx_tcp_socket_establish_notify, nx_tcp_socket_mss_get,
nx_tcp_socket_mss_set, nx_tcp_socket_peer_info_get,
nx_tcp_socket_receive_notify, nx_tcp_socket_timed_wait_callback,
nx_tcp_socket_transmit_configure,
nx_tcp_socket_window_update_notify_set

nx_tcp_socket_mss_set

Set MSS of socket

Prototype

```
UINT nx_tcp_socket_mss_set(NX_TCP_SOCKET *socket_ptr, ULONG mss);
```

Description

This service sets the specified socket's Maximum Segment Size (MSS). Note the MSS value must be within the network interface IP MTU, allowing room for IP and TCP headers.

This service should be used before a TCP socket starts the connection process. If the service is used after a TCP connection is established, the new value has no effect on the connection.

Parameters

socket_ptr	Pointer to previously created socket.
mss	Value of MSS to set.

Return Values

NX_SUCCESS	(0x00)	Successful MSS set.
NX_SIZE_ERROR	(0x09)	Specified MSS value is too large.
NX_NOT_CONNECTED	(0x38)	TCP connection has not been established
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_NOT_ENABLED	(0x14)	TCP is not enabled.
NX_CALLER_ERROR	(0x11)	Caller is not a thread or initialization.

Allowed From

Initialization and threads

Preemption Possible

No

Example

```
/* Set the MSS of the socket "my_socket" to 1000 bytes. */  
status = nx_tcp_socket_mss_set(&my_socket, 1000);  
  
/* If status is NX_SUCCESS, the MSS of "my_socket" is 1000 bytes. */
```

`nx_tcp_socket_establish_notify`, `nx_tcp_socket_mss_get`,
`nx_tcp_socket_mss_peer_get`, `nx_tcp_socket_peer_info_get`,
`nx_tcp_socket_receive_notify`, `nx_tcp_socket_timed_wait_callback`,
`nx_tcp_socket_transmit_configure`,
`nx_tcp_socket_window_update_notify_set`

nx_tcp_socket_peer_info_get

Retrieve information about peer TCP socket

Prototype

```
UINT nx_tcp_socket_peer_info_get(NX_TCP_SOCKET *socket_ptr,
                                ULONG *peer_ip_address,
                                ULONG *peer_port);
```

Description

This service retrieves peer IP address and port information for the connected TCP socket over IP network.

Parameters

socket_ptr	Pointer to previously created TCP socket.
peer_ip_address	Pointer to destination for peer IP address, in host byte order.
peer_port	Pointer to destination for peer port number, in host byte order.

Return Values

NX_SUCCESS	(0x00)	Service executes successfully. Peer IP address and port number are returned to the caller.
NX_NOT_CONNECTED	(0x38)	Socket is not in a connected state.
NX_PTR_ERROR	(0x07)	Invalid pointers.
NX_NOT_ENABLED	(0x14)	TCP is not enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Obtain peer IP address and port on the specified TCP socket. */
status = nx_tcp_socket_peer_info_get(&my_socket, &peer_ip_address,
                                     &peer_port);

/* If status = NX_SUCCESS, the data was successfully obtained. */
```

See Also

`nx_tcp_socket_establish_notify`, `nx_tcp_socket_mss_get`,
`nx_tcp_socket_mss_peer_get`, `nx_tcp_socket_mss_set`,
`nx_tcp_socket_receive_notify`, `nx_tcp_socket_timed_wait_callback`,
`nx_tcp_socket_transmit_configure`,
`nx_tcp_socket_window_update_notify_set`

nx_tcp_socket_receive

Receive data from TCP socket

Prototype

```
UINT nx_tcp_socket_receive(NX_TCP_SOCKET *socket_ptr,
                           NX_PACKET **packet_ptr,
                           ULONG wait_option);
```

Description

This service receives TCP data from the specified socket. If no data are queued on the specified socket, the caller suspends based on the supplied wait option.

If NX_SUCCESS is returned, the application is responsible for releasing the received packet when it is no longer needed.

Parameters

socket_ptr	Pointer to previously created TCP socket instance.
packet_ptr	Pointer to TCP packet pointer.
wait_option	Defines how the service behaves if no data are currently queued on this socket. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful socket data receive.
NX_NOT_BOUND	(0x24)	Socket is not bound yet.
NX_NO_PACKET	(0x01)	No data received.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to tx_thread_wait_abort.

NX_NOT_CONNECTED	(0x38)	The socket is no longer connected.
NX_PTR_ERROR	(0x07)	Invalid socket or return packet pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Receive a packet from the previously created and connected TCP
   client socket. If no packet is available, wait for 200 timer
   ticks before giving up. */
status = nx_tcp_socket_receive(&client_socket, &packet_ptr, 200);

/* If status is NX_SUCCESS, the received packet is pointed to by
   "packet_ptr". */

```

See Also

 nx_tcp_client_socket_port_get, nx_tcp_client_socket_unbind,
 nx_tcp_enable, nx_tcp_free_port_find, nx_tcp_info_get,
 nx_tcp_server_socket_accept, nx_tcp_server_socket_listen,
 nx_tcp_server_socket_relisten, nx_tcp_server_socket_unaccept,
 nx_tcp_server_socket_unlisten, nx_tcp_socket_bytes_available,
 nx_tcp_socket_create, nx_tcp_socket_delete, nx_tcp_socket_disconnect,
 nx_tcp_socket_info_get, nx_tcp_socket_receive_queue_max_set,
 nx_tcp_socket_send, nx_tcp_socket_state_wait

nx_tcp_socket_receive_notify

Notify application of received packets

Prototype

```
UINT nx_tcp_socket_receive_notify(NX_TCP_SOCKET *socket_ptr, VOID
                                  (*tcp_receive_notify)
                                  (NX_TCP_SOCKET *socket_ptr));
```

Description

This service configures the receive notify function pointer with the callback function specified by the application. This callback function is then called whenever one or more packets are received on the socket. If a NX_NULL pointer is supplied, the notify function is disabled.

Parameters

socket_ptr	Pointer to the TCP socket.
tcp_receive_notify	Application callback function pointer that is called when one or more packets are received on the socket.

Return Values

NX_SUCCESS	(0x00)	Successful socket receive notify.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	TCP feature is not enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Setup a receive packet callback function for the "client_socket"
   socket. */
status = nx_tcp_socket_receive_notify(&client_socket,
                                      my_receive_notify);

/* If status is NX_SUCCESS, NetX will call the function named
   "my_receive_notify" whenever one or more packets are received for
   "client_socket". */
```

See Also

`nx_tcp_socket_disconnect_complete_notify`,
`nx_tcp_socket_establish_notify`, `nx_tcp_socket_mss_get`,
`nx_tcp_socket_mss_peer_get`, `nx_tcp_socket_mss_set`,
`nx_tcp_socket_peer_info_get`, `nx_tcp_socket_timed_wait_callback`,
`nx_tcp_socket_transmit_configure`,
`nx_tcp_socket_window_update_notify_set`

nx_tcp_socket_send

Send data through a TCP socket

Prototype

```
UINT nx_tcp_socket_send(NX_TCP_SOCKET *socket_ptr,
                        NX_PACKET *packet_ptr,
                        ULONG wait_option);
```

Description

This service sends TCP data through a previously connected TCP socket. If the receiver's last advertised window size is less than this request, the service optionally suspends based on the wait option specified. This service guarantees that no packet data larger than MSS is sent to the IP layer.

Unless an error is returned, the application should not release the packet after this call. Doing so will cause unpredictable results because the network driver will also try to release the packet after transmission.

Parameters

socket_ptr	Pointer to previously connected TCP socket instance.						
packet_ptr	TCP data packet pointer.						
wait_option	Defines how the service behaves if the request is greater than the window size of the receiver. The wait options are defined as follows: <table data-bbox="641 1119 1150 1237"> <tr> <td>NX_NO_WAIT</td><td>(0x00000000)</td></tr> <tr> <td>NX_WAIT_FOREVER</td><td>(0xFFFFFFFF)</td></tr> <tr> <td>timeout value in ticks</td><td>(0x00000001 through 0xFFFFFFFF)</td></tr> </table>	NX_NO_WAIT	(0x00000000)	NX_WAIT_FOREVER	(0xFFFFFFFF)	timeout value in ticks	(0x00000001 through 0xFFFFFFFF)
NX_NO_WAIT	(0x00000000)						
NX_WAIT_FOREVER	(0xFFFFFFFF)						
timeout value in ticks	(0x00000001 through 0xFFFFFFFF)						

Return Values

NX_SUCCESS	(0x00)	Successful socket send.
NX_NOT_BOUND	(0x24)	Socket was not bound to any port.
NX_NO_INTERFACE_ADDRESS	(0x50)	No suitable outgoing interface found.
NX_NOT_CONNECTED	(0x38)	Socket is no longer connected.
NX_WINDOW_OVERFLOW	(0x39)	Request is greater than receiver's advertised window size in bytes.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_INVALID_PACKET	(0x12)	Packet is not allocated.
NX_TX_QUEUE_DEPTH	(0x49)	Maximum transmit queue depth has been reached.
NX_OVERFLOW	(0x03)	Packet append pointer is invalid.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_UNDERFLOW	(0x02)	Packet prepend pointer is invalid.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Send a packet out on the previously created and connected TCP
   socket. If the receive window on the other side of the connection
   is less than the packet size, wait 200 timer ticks before giving
   up. */
status = nx_tcp_socket_send(&client_socket, packet_ptr, 200);

/* If status is NX_SUCCESS, the packet has been sent! */
```

`nx_tcp_socket_receive_queue_max_set`, `nx_tcp_socket_state_wait`

nx_tcp_socket_state_wait

Wait for TCP socket to enter specific state

Prototype

```
UINT nx_tcp_socket_state_wait(NX_TCP_SOCKET *socket_ptr,
                              UINT desired_state,
                              ULONG wait_option);
```

Description

This service waits for the socket to enter the desired state. If the socket is not in the desired state, the service suspends according to the supplied wait option.

Parameters

socket_ptr	Pointer to previously connected TCP socket instance.
desired_state	Desired TCP state. Valid TCP socket states are defined as follows: <div><div>NX_TCP_CLOSED(0x01)</div><div>NX_TCP_LISTEN_STATE(0x02)</div><div>NX_TCP_SYN_SENT(0x03)</div><div>NX_TCP_SYN_RECEIVED(0x04)</div><div>NX_TCP_ESTABLISHED(0x05)</div><div>NX_TCP_CLOSE_WAIT(0x06)</div><div>NX_TCP_FIN_WAIT_1(0x07)</div><div>NX_TCP_FIN_WAIT_2(0x08)</div><div>NX_TCP_CLOSING(0x09)</div><div>NX_TCP_TIMED_WAIT(0x0A)</div><div>NX_TCP_LAST_ACK(0x0B)</div></div>
wait_option	Defines how the service behaves if the requested state is not present. The wait options are defined as follows: <div><div>NX_NO_WAIT(0x00000000)</div><div>NX_WAIT_FOREVER(0xFFFFFFFF)</div><div>timeout value in ticks (0x00000001 through 0xFFFFFFFFFE)</div></div>

Return Values

NX_SUCCESS	(0x00)	Successful state wait.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.

NX_NOT_SUCCESSFUL	(0x43)	State not present within the specified wait time.
NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_OPTION_ERROR	(0x0A)	The desired socket state is invalid.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Wait 300 timer ticks for the previously created socket to enter
   the established state in the TCP state machine. */
status = nx_tcp_socket_state_wait(&client_socket,
                                   NX_TCP_ESTABLISHED, 300);

/* If status is NX_SUCCESS, the socket is now in the established
   state! */

```

`nx_tcp_socket_timed_wait_callback`

Install callback for timed wait state

Prototype

```
UINT nx_tcp_socket_timed_wait_callback(NX_TCP_SOCKET *socket_ptr,
                                       VOID (*tcp_timed_wait_callback)
                                       (NX_TCP_SOCKET *socket_ptr))
```

Description

This service registers a callback function which is invoked when the TCP socket is in timed wait state. To use this service, the NetX library must be built with the option ***NX_ENABLE_EXTENDED_NOTIFY*** defined.

Parameters

<code>socket_ptr</code>	Pointer to previously connected client or server socket instance.
<code>tcp_timed_wait_callback</code>	The timed wait callback function

Return Values

<code>NX_SUCCESS</code>	(0x00)	Successfully registers the callback function socket
<code>NX_NOT_SUPPORTED</code>	(0x4B)	NetX library is built without the extended notify feature enabled.
<code>NX_PTR_ERROR</code>	(0x07)	Invalid socket pointer.
<code>NX_CALLER_ERROR</code>	(0x11)	Invalid caller of this service.
<code>NX_NOT_ENABLED</code>	(0x14)	TCP feature is not enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Install the timed wait callback function */  
nx_tcp_socket_timed_wait_callback(&client_socket, callback);
```

nx_tcp_socket_transmit_configure

Configure socket's transmit parameters

Prototype

```
UINT nx_tcp_socket_transmit_configure(NX_TCP_SOCKET *socket_ptr,
                                     ULONG max_queue_depth,
                                     ULONG timeout,
                                     ULONG max_retries,
                                     ULONG timeout_shift);
```

Description

This service configures various transmit parameters of the specified TCP socket.

Parameters

socket_ptr	Pointer to the TCP socket.
max_queue_depth	Maximum number of packets allowed to be queued for transmission.
timeout	Number of ThreadX timer ticks an ACK is waited for before the packet is sent again.
max_retries	Maximum number of retries allowed.
timeout_shift	Value to shift the timeout for each subsequent retry. A value of 0, results in the same timeout between successive retries. A value of 1, doubles the timeout between retries.

Return Values

NX_SUCCESS	(0x00)	Successful transmit socket configure.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_OPTION_ERROR	(0x0a)	Invalid queue depth option.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	TCP feature is not enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Configure the "client_socket" for a maximum transmit queue depth
   of 12, 100 tick timeouts, a maximum of 20 retries, and a timeout
   double on each successive retry. */
status = nx_tcp_socket_transmit_configure(&client_socket,12,100,20,
                                          1);

/* If status is NX_SUCCESS, the socket's transmit retry has been
   configured. */
```

`nx_tcp_socket_timed_wait_callback`,
`nx_tcp_socket_window_update_notify_set`

`nx_tcp_socket_window_update_notify_set`

Notify application of window size updates

Prototype

```
UINT nx_tcp_socket_window_update_notify_set(NX_TCP_SOCKET
                                             *socket_ptr,
                                             VOID (*tcp_window_update_notify)
                                             (NX_TCP_SOCKET *socket_ptr))
```

Description

This service installs a socket window update callback routine. This routine is called automatically whenever the specified socket receives a packet indicating an increase in the window size of the remote host.

Parameters

socket_ptr	Pointer to previously created TCP socket.
tcp_window_update_notify	Callback routine to be called when the window size changes. A value of NULL disables the window change update.

Return Values

NX_SUCCESS	(0x00)	Callback routine is installed on the socket.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_PTR_ERROR	(0x07)	Invalid pointers.
NX_NOT_ENABLED	(0x14)	TCP feature is not enabled.

Allowed From

Initialization, threads

Preemption Possible

No

Example

```
/* Set the function pointer to the windows update callback after creating the
   socket. */
status = nx_tcp_socket_window_update_notify_set(&data_socket,
                                                my_windows_update_callback);
/* Define the window callback function in the host application. */
void my_windows_update_callback(NX_TCP_SOCKET *data_socket)
{
    /* Process update on increase TCP transmit socket window size. */
    return;
}
```

nx_udp_free_port_find

Find next available UDP port

Prototype

```
UINT nx_udp_free_port_find(NX_IP *ip_ptr, UINT port,
                           UINT *free_port_ptr);
```

Description

This service looks for a free UDP port (unbound) starting from the application supplied port number. The search logic will wrap around if the search reaches the maximum port value of 0xFFFF. If the search is successful, the free port is returned in the variable pointed to by *free_port_ptr*.

 *This service can be called from another thread and can have the same port returned. To prevent this race condition, the application may wish to place this service and the actual socket bind under the protection of a mutex.*

Parameters

ip_ptr	Pointer to previously created IP instance.
port	Port number to start search (1 through 0xFFFF).
free_port_ptr	Pointer to the destination free port return variable.

Return Values

NX_SUCCESS	(0x00)	Successful free port find.
NX_NO_FREE_PORTS	(0x45)	No free ports found.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.
NX_INVALID_PORT	(0x46)	Specified port number is invalid.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Locate a free UDP port, starting at port 12, on a previously
   created IP instance. */
status = nx_udp_free_port_find(&ip_0, 12, &free_port);

/* If status is NX_SUCCESS pointer, "free_port" identifies the next
   free UDP port on the IP instance. */
```

`nx_udp_source_extract`

nx_udp_info_get

Retrieve information about UDP activities

Prototype

```
UINT nx_udp_info_get(NX_IP *ip_ptr,
                    ULONG *udp_packets_sent,
                    ULONG *udp_bytes_sent,
                    ULONG *udp_packets_received,
                    ULONG *udp_bytes_received,
                    ULONG *udp_invalid_packets,
                    ULONG *udp_receive_packets_dropped,
                    ULONG *udp_checksum_errors);
```

Description

This service retrieves information about UDP activities for the specified IP instance.

i If a destination pointer is `NX_NULL`, that particular information is not returned to the caller.

Parameters

<code>ip_ptr</code>	Pointer to previously created IP instance.
<code>udp_packets_sent</code>	Pointer to destination for the total number of UDP packets sent.
<code>udp_bytes_sent</code>	Pointer to destination for the total number of UDP bytes sent.
<code>udp_packets_received</code>	Pointer to destination of the total number of UDP packets received.
<code>udp_bytes_received</code>	Pointer to destination of the total number of UDP bytes received.
<code>udp_invalid_packets</code>	Pointer to destination of the total number of invalid UDP packets.
<code>udp_receive_packets_dropped</code>	Pointer to destination of the total number of UDP receive packets dropped.
<code>udp_checksum_errors</code>	Pointer to destination of the total number of UDP packets with checksum errors.

Return Values

NX_SUCCESS	(0x00)	Successful UDP information retrieval.
NX_PTR_ERROR	(0x07)	Invalid IP pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads, and timers

Preemption Possible

No

Example

```
/* Retrieve UDP information from previously created IP Instance
   ip_0. */
status = nx_udp_info_get(&ip_0, &udp_packets_sent,
                        &udp_bytes_sent,
                        &udp_packets_received,
                        &udp_bytes_received,
                        &udp_invalid_packets,
                        &udp_receive_packets_dropped,
                        &udp_checksum_errors);

/* If status is NX_SUCCESS, UDP information was retrieved. */
```

`nx_udp_source_extract`

nx_udp_packet_info_extract

Extract network parameters from UDP packet

Prototype

```
UINT nx_udp_packet_info_extract(NX_PACKET *packet_ptr,
                                ULONG *ip_address,
                                UINT *protocol,
                                UINT *port,
                                UINT *interface_index);
```

Description

This service extracts network parameters, such as IP address, peer port number, protocol type (this service always returns UDP type) from a packet received on an incoming interface.

Parameters

packet_ptr	Pointer to packet.
ip_address	Pointer to sender IP address.
protocol	Pointer to protocol (UDP).
port	Pointer to sender's port number.
interface_index	Pointer to receiving interface index.

Return Values

NX_SUCCESS	(0x00)	Packet interface data successfully extracted.
NX_INVALID_PACKET	(0x12)	Packet does not contain IP frame.
NX_PTR_ERROR	(0x07)	Invalid pointer input
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Extract network data from UDP packet interface.*/
status = nx_udp_packet_info_extract( packet_ptr, &ip_address,
                                     &protocol, &port,
                                     &interface_index)

/* If status is NX_SUCCESS packet data was successfully
   retrieved. */
```

`nx_udp_socket_port_get`, `nx_udp_socket_receive`,
`nx_udp_socket_receive_notify`, `nx_udp_socket_send`,
`nx_udp_socket_interface_send`, `nx_udp_socket_unbind`,
`nx_udp_source_extract`

nx_udp_socket_bind

Bind UDP socket to UDP port

Prototype

```
UINT nx_udp_socket_bind(NX_UDP_SOCKET *socket_ptr, UINT port,
                        ULONG wait_option);
```

Description

This service binds the previously created UDP socket to the specified UDP port. Valid UDP sockets range from 0 through 0xFFFF. If the requested port number is bound to another socket, this service waits for specified period of time for the socket to unbind from the port number.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
port	Port number to bind to (1 through 0xFFFF). If port number is NX_ANY_PORT (0x0000), the IP instance will search for the next free port and use that for the binding.
wait_option	Defines how the service behaves if the port is already bound to another socket. The wait options are defined as follows: NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFFE)

Return Values

NX_SUCCESS	(0x00)	Successful socket bind.
NX_ALREADY_BOUND	(0x22)	This socket is already bound to another port.
NX_PORT_UNAVAILABLE	(0x23)	Port is already bound to a different socket.
NX_NO_FREE_PORTS	(0x45)	No free port.

NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_INVALID_PORT	(0x46)	Invalid port specified.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Bind the previously created UDP socket to port 12 on the
   previously created IP instance. If the port is already bound,
   wait for 300 timer ticks before giving up. */
status = nx_udp_socket_bind(&udp_socket, 12, 300);

/* If status is NX_SUCCESS, the UDP socket is now bound to
   port 12.*/

```

 nx_udp_packet_info_extract, nx_udp_socket_bytes_available,
 nx_udp_socket_checksum_disable, nx_udp_socket_checksum_enable,
 nx_udp_socket_create, nx_udp_socket_delete, nx_udp_socket_info_get,
 nx_udp_socket_port_get, nx_udp_socket_receive,
 nx_udp_socket_receive_notify, nx_udp_socket_send,
 nx_udp_socket_interface_send, nx_udp_socket_unbind,
 nx_udp_source_extract

nx_udp_socket_bytes_available

Retrieves number of bytes available for retrieval

Prototype

```
UINT nx_udp_socket_bytes_available(NX_UDP_SOCKET *socket_ptr,
                                   ULONG *bytes_available);
```

Description

This service retrieves number of bytes available for reception in the specified UDP socket.

Parameters

socket_ptr	Pointer to previously created UDP socket.
bytes_available	Pointer to destination for bytes available.

Return Values

NX_SUCCESS	(0x00)	Successful bytes available retrieval.
NX_NOT_SUCCESSFUL	(0x43)	Socket not bound to a port.
NX_PTR_ERROR	(0x07)	Invalid pointers.
NX_NOT_ENABLED	(0x14)	UDP feature is not enabled.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Get the bytes available for retrieval from the UDP socket. */
status = nx_udp_socket_bytes_available(&my_socket,
                                       &bytes_available);

/* If status == NX_SUCCESS, the number of bytes was successfully
   retrieved.*/
```

`nx_udp_socket_create`, `nx_udp_socket_delete`, `nx_udp_socket_info_get`,
`nx_udp_socket_port_get`, `nx_udp_socket_receive`,
`nx_udp_socket_receive_notify`, `nx_udp_socket_send`,
`nx_udp_socket_interface_send`, `nx_udp_socket_unbind`,
`nx_udp_source_extract`

nx_udp_socket_checksum_disable

Disable checksum for UDP socket

Prototype

```
UINT nx_udp_socket_checksum_disable(NX_UDP_SOCKET *socket_ptr);
```

Description

This service disables the checksum logic for sending and receiving packets on the specified UDP socket. When the checksum logic is disabled, a value of zero is loaded into the UDP header's checksum field for all packets sent through this socket. A zero-value checksum value in the UDP header signals the receiver that checksum is not computed for this packet.

Also note that this has no effect if ***NX_DISABLE_UDP_RX_CHECKSUM*** and ***NX_DISABLE_UDP_TX_CHECKSUM*** are defined when receiving and sending UDP packets respectively,

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
------------	--

Return Values

NX_SUCCESS	(0x00)	Successful socket checksum disable.
NX_NOT_BOUND	(0x24)	Socket is not bound.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads, timer

Preemption Possible

No

Example

```
/* Disable the UDP checksum logic for packets sent on this socket. */
status = nx_udp_socket_checksum_disable(&udp_socket);

/* If status is NX_SUCCESS, outgoing packets will not have a checksum
   calculated. */
```

`nx_udp_socket_receive_notify`, `nx_udp_socket_send`,
`nx_udp_socket_interface_send`, `nx_udp_socket_unbind`,
`nx_udp_source_extract`

nx_udp_socket_checksum_enable

Enable checksum for UDP socket

Prototype

```
UINT nx_udp_socket_checksum_enable(NX_UDP_SOCKET *socket_ptr);
```

Description

This service enables the checksum logic for sending and receiving packets on the specified UDP socket. The checksum covers the entire UDP data area as well as a pseudo IP header.

Also note that this has no effect if **NX_DISABLE_UDP_RX_CHECKSUM** and **NX_DISABLE_UDP_TX_CHECKSUM** are defined when receiving and sending UDP packets respectively.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
------------	--

Return Values

NX_SUCCESS	(0x00)	Successful socket checksum enable.
NX_NOT_BOUND	(0x24)	Socket is not bound.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads, timer

Preemption Possible

No

Example

```
/* Enable the UDP checksum logic for packets sent on this socket. */
status = nx_udp_socket_checksum_enable(&udp_socket);

/* If status is NX_SUCCESS, outgoing packets will have a checksum
   calculated. */
```

`nx_udp_source_extract`

nx_udp_socket_create

Create UDP socket

Prototype

```
UINT nx_udp_socket_create(NX_IP *ip_ptr,
                          NX_UDP_SOCKET *socket_ptr, CHAR *name,
                          ULONG type_of_service, ULONG fragment,
                          UINT time_to_live, ULONG queue_maximum);
```

Description

This service creates a UDP socket for the specified IP instance.

Parameters

ip_ptr	Pointer to previously created IP instance.
socket_ptr	Pointer to new UDP socket control bloc.
name	Application name for this UDP socket.
type_of_service	Defines the type of service for the transmission, legal values are as follows: NX_IP_NORMAL (0x00000000) NX_IP_MIN_DELAY (0x00100000) NX_IP_MAX_DATA (0x00080000) NX_IP_MAX_RELIABLE (0x00040000) NX_IP_MIN_COST (0x00020000)
fragment	Specifies whether or not IP fragmenting is allowed. If NX_FRAGMENT_OKAY (0x0) is specified, IP fragmenting is allowed. If NX_DONT_FRAGMENT (0x4000) is specified, IP fragmenting is disabled.
time_to_live	Specifies the 8-bit value that defines how many routers this packet can pass before being thrown away. The default value is specified by NX_IP_TIME_TO_LIVE.
queue_maximum	Defines the maximum number of UDP datagrams that can be queued for this socket. After the queue limit is reached, for every new packet received the oldest UDP packet is released.

Return Values

NX_SUCCESS	(0x00)	Successful UDP socket create.
NX_OPTION_ERROR	(0x0A)	Invalid type-of-service, fragment, or time-to-live option.
NX_PTR_ERROR	(0x07)	Invalid IP or socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization and Threads

Preemption Possible

No

Example

```
/* Create a UDP socket with a maximum receive queue of 30 packets.*/
status = nx_udp_socket_create(&ip_0, &udp_socket, "Sample UDP
                                Socket",
                                NX_IP_NORMAL, NX_FRAGMENT_OKAY, 0x80,
                                30);

/* If status is NX_SUCCESS, the new UDP socket has been created and
   is ready for binding. */
```

 nx_udp_socket_unbind, nx_udp_source_extract

nx_udp_socket_delete

Delete UDP socket

Prototype

```
UINT nx_udp_socket_delete(NX_UDP_SOCKET *socket_ptr);
```

Description

This service deletes a previously created UDP socket. If the socket was bound to a port, the socket must be unbound first.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
------------	--

Return Values

NX_SUCCESS	(0x00)	Successful socket delete.
NX_STILL_BOUND	(0x42)	Socket is still bound.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Delete a previously created UDP socket. */
status = nx_udp_socket_delete(&udp_socket);

/* If status is NX_SUCCESS, the previously created UDP socket has
   been deleted. */
```

nx_udp_socket_send, nx_udp_socket_interface_send,
nx_udp_socket_unbind, nx_udp_source_extract

nx_udp_socket_info_get

Retrieve information about UDP socket activities

Prototype

```
UINT nx_udp_socket_info_get(NX_UDP_SOCKET *socket_ptr,
                             ULONG *udp_packets_sent,
                             ULONG *udp_bytes_sent,
                             ULONG *udp_packets_received,
                             ULONG *udp_bytes_received,
                             ULONG *udp_packets_queued,
                             ULONG *udp_receive_packets_dropped,
                             ULONG *udp_checksum_errors);
```

Description

This service retrieves information about UDP socket activities for the specified UDP socket instance.

i If a destination pointer is NX_NULL, that particular information is not returned to the caller.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
udp_packets_sent	Pointer to destination for the total number of UDP packets sent on socket.
udp_bytes_sent	Pointer to destination for the total number of UDP bytes sent on socket.
udp_packets_received	Pointer to destination of the total number of UDP packets received on socket.
udp_bytes_received	Pointer to destination of the total number of UDP bytes received on socket.
udp_packets_queued	Pointer to destination of the total number of queued UDP packets on socket.
udp_receive_packets_dropped	Pointer to destination of the total number of UDP receive packets dropped for socket due to queue size being exceeded.
udp_checksum_errors	Pointer to destination of the total number of UDP packets with checksum errors on socket.

Return Values

NX_SUCCESS	(0x00)	Successful UDP socket information retrieval.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Initialization, threads, and timers

Preemption Possible

No

Example

```
/* Retrieve UDP socket information from socket 0.*/
status = nx_udp_socket_info_get(&socket_0,
                                &udp_packets_sent,
                                &udp_bytes_sent,
                                &udp_packets_received,
                                &udp_bytes_received,
                                &udp_queued_packets,
                                &udp_receive_packets_dropped,
                                &udp_checksum_errors);

/* If status is NX_SUCCESS, UDP socket information was retrieved.*/
```

 nx_udp_socket_bytes_available, nx_udp_socket_checksum_disable,
 nx_udp_socket_checksum_enable, nx_udp_socket_create,
 nx_udp_socket_delete, nx_udp_socket_port_get,
 nx_udp_socket_receive, nx_udp_socket_receive_notify,
 nx_udp_socket_send, nx_udp_socket_interface_send,
 nx_udp_socket_unbind, nx_udp_source_extract

nx_udp_socket_port_get

Pick up port number bound to UDP socket

Prototype

```
UINT nx_udp_socket_port_get(NX_UDP_SOCKET *socket_ptr,
                             UINT *port_ptr);
```

Description

This service retrieves the port number associated with the socket, which is useful to find the port allocated by NetX in situations where the NX_ANY_PORT was specified at the time the socket was bound.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
port_ptr	Pointer to destination for the return port number. Valid port numbers are (1- 0xFFFF).

Return Values

NX_SUCCESS	(0x00)	Successful socket bind.
NX_NOT_BOUND	(0x24)	This socket is not bound to a port.
NX_PTR_ERROR	(0x07)	Invalid socket pointer or port return pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```
/* Get the port number of created and bound UDP socket. */
status = nx_udp_socket_port_get(&udp_socket, &port);

/* If status is NX_SUCCESS, the port variable contains the port this
   socket is bound to. */
```

nx_udp_socket_receive

Receive datagram from UDP socket

Prototype

```
UINT nx_udp_socket_receive(NX_UDP_SOCKET *socket_ptr,
                           NX_PACKET **packet_ptr,
                           ULONG wait_option);
```

Description

This service receives an UDP datagram from the specified socket. If no datagram is queued on the specified socket, the caller suspends based on the supplied wait option.

If NX_SUCCESS is returned, the application is responsible for releasing the received packet when it is no longer needed.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
packet_ptr	Pointer to UDP datagram packet pointer.
wait_option	Defines how the service behaves if a datagram is not currently queued on this socket. The wait options are defined as follows: <div>NX_NO_WAIT (0x00000000) NX_WAIT_FOREVER (0xFFFFFFFF) timeout value in ticks (0x00000001 through 0xFFFFFFFF)</div>

Return Values

NX_SUCCESS	(0x00)	Successful socket receive.
NX_NOT_BOUND	(0x24)	Socket was not bound to any port.
NX_NO_PACKET	(0x01)	There was no UDP datagram to receive.

NX_WAIT_ABORTED	(0x1A)	Requested suspension was aborted by a call to <i>tx_thread_wait_abort</i> .
NX_PTR_ERROR	(0x07)	Invalid socket or packet return pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

No

Example

```

/* Receive a packet from a previously created and bound UDP socket.
   If no packets are currently available, wait for 500 timer ticks
   before giving up. */
status = nx_udp_socket_receive(&udp_socket, &packet_ptr, 500);

/* If status is NX_SUCCESS, the received UDP packet is pointed to by
   packet_ptr. */

```

 nx_udp_socket_send, nx_udp_socket_interface_send,
 nx_udp_socket_unbind, nx_udp_source_extract

nx_udp_socket_receive_notify

Notify application of each received packet

Prototype

```
UINT nx_udp_socket_receive_notify(NX_UDP_SOCKET *socket_ptr,
                                  VOID (*udp_receive_notify)
                                  (NX_UDP_SOCKET *socket_ptr));
```

Description

This service sets the receive notify function pointer to the callback function specified by the application. This callback function is then called whenever a packet is received on the socket. If a NX_NULL pointer is supplied, the receive notify function is disabled.

Parameters

socket_ptr	Pointer to the UDP socket.
udp_receive_notify	Application callback function pointer that is called when a packet is received on the socket.

Return Values

NX_SUCCESS	(0x00)	Successfully set socket receive notify function.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.

Allowed From

Initialization, threads, timers, and ISRs

Preemption Possible

No

Example

```
/* Setup a receive packet callback function for the "udp_socket"
   socket. */
status = nx_udp_socket_receive_notify(&udp_socket,
                                       my_receive_notify);

/* If status is NX_SUCCESS, NetX will call the function named
   "my_receive_notify" whenever a packet is received for
   "udp_socket". */
```

`nx_udp_socket_port_get`, `nx_udp_socket_receive`, `nx_udp_socket_send`,
`nx_udp_socket_interface_send`, `nx_udp_socket_unbind`,
`nx_udp_source_extract`

nx_udp_socket_send

Send a UDP Datagram

Prototype

```
UINT nx_udp_socket_send(NX_UDP_SOCKET *socket_ptr,
                        NX_PACKET *packet_ptr,
                        ULONG ip_address,
                        UINT port);
```

Description

This service sends a UDP datagram through a previously created and bound UDP socket. NetX finds a suitable local IP address as source address based on the destination IP address. To specify a specific interface and source IP address, the application should use the **nx_udp_socket_interface_send** service.

Note that this service returns immediately regardless of whether the UDP datagram was successfully sent.

The socket must be bound to a local port.

Parameters

socket_ptr	Pointer to previously created UDP socket instance
packet_ptr	UDP datagram packet pointer
ip_address	Destination IP address
port	Valid destination port number between 1 and 0xFFFF, in host byte order

Return Values

NX_SUCCESS	(0x00)	Successful UDP socket send
NX_NOT_BOUND	(0x24)	Socket not bound to any port
NX_NO_INTERFACE_ADDRESS	(0x50)	No suitable outgoing interface can be found.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid server IP address
NX_UNDERFLOW	(0x02)	Not enough room for UDP header in the packet

NX_OVERFLOW	(0x03)	Packet append pointer is invalid
NX_PTR_ERROR	(0x07)	Invalid socket pointer
NX_CALLER_ERROR	(0x11)	Invalid caller of this service
NX_NOT_ENABLED	(0x14)	UDP has not been enabled
NX_INVALID_PORT	(0x46)	Port number is not within a valid range

Allowed From

Threads

Preemption Possible

No

Example

```

ULONG  server_address;

/* Set the UDP Client IP address. */
server_address = IP_ADDRESS(1,2,3,5);

/* Send a packet to the UDP server at server_address on port 12. */
status = nx_udp_socket_send(&client_socket, packet_ptr,
                             server_address, 12);

/* If status == NX_SUCCESS, the application successfully transmitted
   the packet out the UDP socket to its peer. */

```

 nx_udp_packet_info_extract, nx_udp_socket_bind,
 nx_udp_socket_bytes_available, nx_udp_socket_checksum_disable,
 nx_udp_socket_checksum_enable, nx_udp_socket_create,
 nx_udp_socket_delete, nx_udp_socket_info_get,
 nx_udp_socket_port_get, nx_udp_socket_receive,
 nx_udp_socket_receive_notify, nx_udp_socket_interface_send,
 nx_udp_socket_unbind, nx_udp_source_extract

nx_udp_socket_interface_send

Send datagram through UDP socket

Prototype

```
UINT nx_udp_socket_interface_send(NX_UDP_SOCKET *socket_ptr,
                                  NX_PACKET *packet_ptr,
                                  ULONG ip_address,
                                  UINT port,
                                  UINT address_index);
```

Description

This service sends a UDP datagram through a previously created and bound UDP socket through the network interface with the specified IP address as the source address. Note that service returns immediately, regardless of whether or not the UDP datagram was successfully sent.

Parameters

socket_ptr	Socket to transmit the packet out on.
packet_ptr	Pointer to packet to transmit.
ip_address	Destination IP address to send packet.
port	Destination port.
address_index	Index of the address associated with the interface to send packet on.

Return Values

NX_SUCCESS	(0x00)	Packet successfully sent.
NX_NOT_BOUND	(0x24)	Socket not bound to a port.
NX_IP_ADDRESS_ERROR	(0x21)	Invalid IP address.
NX_NOT_ENABLED	(0x14)	UDP processing not enabled.
NX_PTR_ERROR	(0x07)	Invalid pointer.
NX_OVERFLOW	(0x03)	Invalid packet append pointer.
NX_UNDERFLOW	(0x02)	Invalid packet prepend pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.

NX_INVALID_INTERFACE	(0x4C)	Invalid address index.
NX_INVALID_PORT	(0x46)	Port number exceeds maximum port number.

Allowed From

Threads

Preemption Possible

No

Example

```
#define ADDRESS_INDEX 1
/* Send packet out on port 80 to the specified destination IP on the
   interface at index 1 in the IP task interface list. */

status = nx_udp_packet_interface_send(socket_ptr, packet_ptr,
                                     destination_ip, 80,
                                     ADDRESS_INDEX);

/* If status is NX_SUCCESS packet was successfully transmitted. */
```

 nx_udp_socket_port_get, nx_udp_socket_receive,
 nx_udp_socket_receive_notify, nx_udp_socket_send,
 nx_udp_socket_unbind

nx_udp_socket_unbind

Unbind UDP socket from UDP port

Prototype

```
UINT nx_udp_socket_unbind(NX_UDP_SOCKET *socket_ptr);
```

Description

This service releases the binding between the UDP socket and a UDP port. Any received packets stored in the receive queue are released as part of the unbind operation.

If there are other threads waiting to bind another socket to the unbound port, the first suspended thread is then bound to the newly unbound port.

Parameters

socket_ptr	Pointer to previously created UDP socket instance.
------------	--

Return Values

NX_SUCCESS	(0x00)	Successful socket unbind.
NX_NOT_BOUND	(0x24)	Socket was not bound to any port.
NX_PTR_ERROR	(0x07)	Invalid socket pointer.
NX_CALLER_ERROR	(0x11)	Invalid caller of this service.
NX_NOT_ENABLED	(0x14)	This component has not been enabled.

Allowed From

Threads

Preemption Possible

Yes

Example

```
/* Unbind the previously bound UDP socket. */
status = nx_udp_socket_unbind(&udp_socket);

/* If status is NX_SUCCESS, the previously bound socket is now
   unbound. */
```

nx_udp_source_extract

Extract IP and sending port from UDP datagram

Prototype

```
UINT nx_udp_source_extract(NX_PACKET *packet_ptr,
                           ULONG *ip_address, UINT *port);
```

Description

This service extracts the sender's IP and port number from the IP and UDP headers of the supplied UDP datagram.

Parameters

packet_ptr	UDP datagram packet pointer.
ip_address	Valid pointer to the return IP address variable.
port	Valid pointer to the return port variable.

Return Values

NX_SUCCESS	(0x00)	Successful source IP/port extraction.
NX_INVALID_PACKET	(0x12)	The supplied packet is invalid.
NX_PTR_ERROR	(0x07)	Invalid packet or IP or port destination.

Allowed From

Initialization, threads, timers, ISR

Preemption Possible

No

Example

```
/* Extract the IP and port information from the sender of the UDP
   packet. */
status = nx_udp_source_extract(packet_ptr, &sender_ip_address,
&sender_port);

/* If status is NX_SUCCESS, the sender IP and port information has
   been stored in sender_ip_address and sender_port respectively.*/
```

NetX Network Drivers

This chapter contains a description of network drivers for NetX. The information presented is designed to help developers write application-specific network drivers for NetX. The following topics are covered:

- Driver Introduction 354
- Driver Entry 354
- Driver Requests 355
 - Driver Initialization 355
 - Enable Link 357
 - Disable Link 357
 - Uninitialize Link 358
 - Packet Send 359
 - Packet Broadcast 360
 - ARP Send 361
 - ARP Response Send 361
 - RARP Send 362
 - Multicast Group Join 363
 - Multicast Group Leave 364
 - Attach Interface 364
 - Detach Interface 365
 - Get Link Status 365
 - Get Link Speed 366
 - Get Duplex Type 367
 - Get Error Count 367
 - Get Receive Packet Count 368
 - Get Transmit Packet Count 369
 - Get Allocation Errors 369
 - Driver Deferred Processing 370
 - User Commands 370
 - Unimplemented Commands 371
- Driver Output 371
- Driver Input 372
 - Deferred Receive Packet Handling 374
- Example RAM Ethernet Network Driver 374

Driver Introduction

The `NX_IP` structure contains everything to manage a single IP instance. This includes general TCP/IP protocol information as well as the application-specific physical network driver's entry routine. The driver's entry routine is defined during the **`nx_ip_create`** service. Additional devices may be added to the IP instance via the **`nx_ip_interface_attach`** service.

Communication between NetX and the application's network driver is accomplished through the **`NX_IP_DRIVER`** request structure. This structure is most often defined locally on the caller's stack and is therefore released after the driver and calling function return. The structure is defined as follows:

```
typedef struct NX_IP_DRIVER_STRUCT
{
    UINT          nx_ip_driver_command;
    UINT          nx_ip_driver_status;
    ULONG         nx_ip_driver_physical_address_msw;
    ULONG         nx_ip_driver_physical_address_lsw;
    NX_PACKET     *nx_ip_driver_packet;
    ULONG         *nx_ip_driver_return_ptr;
    NX_IP         *nx_ip_driver_ptr;
    NX_INTERFACE  *nx_ip_driver_interface;
} NX_IP_DRIVER;
```

Driver Entry

NetX invokes the network driver entry function for driver initialization and for sending packets and for various control and status operations, including initializing and enabling the network device. NetX issues commands to the network driver by setting the **`nx_ip_driver_command`** field in the **`NX_IP_DRIVER`** request structure. The driver entry function has the following format:

```
VOID my_driver_entry(NX_IP_DRIVER *request);
```

Driver Requests

NetX creates the driver request with a specific command and invokes the driver entry function to execute the command. Because each network driver has a single entry function, NetX makes all requests through the driver request data structure. The ***nx_ip_driver_command*** member of the driver request data structure (***NX_IP_DRIVER***) defines the request. Status information is reported back to the caller in the member ***nx_ip_driver_status***. If this field is ***NX_SUCCESS***, the driver request was completed successfully.

NetX serializes all access to the driver. Therefore, the driver does not need to handle multiple threads asynchronously calling the entry function. Note that the device driver function executes with the IP mutex locked. Therefore the device driver internal function shall not block itself.

Typically the device driver also handles interrupts. Therefore, all driver functions need to be interrupt-safe.

Driver Initialization

Although the actual driver initialization processing is application specific, it usually consists of data structure and physical hardware initialization. The information required from NetX for driver initialization is the IP Maximum Transmission Unit (MTU), which is the number of bytes available to the IP-layer payload, including IP header) and if the physical interface needs logical-to-physical mapping. The driver needs to configure the interface MTU by setting the value in ***nx_interface_ip_mtu_size*** in the ***NX_INTERFACE*** structure.

The device driver also needs to set up the value in ***nx_ip_interface_address_mapping_needed*** in ***NX_INTERFACE*** to inform NetX whether or not interface address mapping is required. If address

mapping is needed, the driver is responsible for configuring the interface with valid MAC address, and supply the MAC address to NetX.

When the network driver receives the NX_LINK INITIALIZE request from NetX, it receives a pointer to the IP control block as part of the NX_IP_DRIVER request control block shown above.

After the application calls ***nx_ip_create***, the IP helper thread sends a driver request with the command set to NX_LINK_INITIALIZE to the driver to initialize its physical network interface. The following NX_IP_DRIVER members are used for the initialize request.

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	NX_LINK_INITIALIZE
<code>nx_ip_driver_ptr</code>	Pointer to the IP instance. This value should be saved by the driver so that the driver function can find the IP instance to operate on.
<code>nx_ip_driver_interface</code>	Pointer to the network interface structure within the IP instance. This information should be saved by the driver. On receiving packets, the driver shall use the interface structure information when sending the packet up the stack.
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to initialize the specified interface to the IP instance, it will return a non-zero error status.

Most of the driver commands are called from the IP helper thread that was created for the IP instance. Therefore the driver routine should avoid performing blocking operations, or the IP helper thread could

stall, causing unbounded delays to applications that rely on the IP thread.

Enable Link

Next, the IP helper thread enables the physical network by setting the driver command to `NX_LINK_ENABLE` in the driver request and sending the request to the network driver. This happens shortly after the IP helper thread completes the initialization request. Enabling the link may be as simple as setting the `nx_interface_link_up` field in the interface instance. But it may also involve manipulation of the physical hardware. The following `NX_IP_DRIVER` members are used for the enable link request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	<code>NX_LINK_ENABLE</code>
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_interface</code>	Pointer to the interface instance
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to enable the specified interface, it will return a non-zero error status.

Disable Link

This request is made by NetX during the deletion of an IP instance by the *`nx_ip_delete`* service. Or an application may issue this command in order to temporarily disable the link in order to save power. This service disables the physical network interface on the IP instance. The processing to disable the link may be as simple as clearing the `nx_interface_link_up` flag in the interface instance. But it may also involve manipulation of the physical hardware. Typically it is a reverse operation of the

Enable Link operation. After the link is disabled, the application request **Enable Link** operation to enable the interface.

The following NX_IP_DRIVER members are used for the disable link request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_DISABLE
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to disable the specified interface in the IP instance, it will return a non-zero error status.

Uninitialize Link

This request is made by NetX during the deletion of an IP instance by the **nx_ip_delete** service. This request uninitialize the interface, and release any resources created during initialization phase. Typically it is a reverse operation of the **Initialize Link** operation. After the interface is uninitialized, the device cannot be used until the interface is initialized again.

The following NX_IP_DRIVER members are used for the disable link request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_UNINITIALIZE
nx_ip_driver_ptr	Pointer to IP instance

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_interface</code>	Pointer to the interface instance
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to uninitialize the specified interface to the IP instance, it will return a non-zero error status.

Packet Send

This request is made during internal IP send processing, which all NetX protocols use to transmit packets (except for ARP, RARP). On receiving the packet send command, the *nx_packet_prepend_ptr* points to the beginning of the packet to be sent, which is the beginning of the IP header. *nx_packet_length* indicates the total size (in bytes) of the data being transmitted. If *nx_packet_next* is valid, the outgoing IP datagram is stored in multiple packets, the driver is required to follow the chained packet and transmit the entire frame. Note that valid data area in each chained packet is stored between *nx_packet_prepend_ptr* and *nx_packet_append_ptr*.

The driver is responsible for constructing physical header. If physical address to IP address mapping is required (such as Ethernet), the IP layer already resolved the MAC address. The destination MAC address is passed from the IP instance, stored in *nx_ip_driver_physical_address_msw* and *nx_ip_driver_physical_address_lsw*.

After adding the physical header, the packet send processing then calls the driver's output function to transmit the packet.

The following NX_IP_DRIVER members are used for the packet send request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_PACKET_SEND
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_packet	Pointer to the packet to send
nx_ip_driver_interface	Pointer to the interface instance.
nx_ip_driver_physical_address_msw	Most significant 32-bits of physical address (only if physical mapping needed)
nx_ip_driver_physical_address_lsw	Least significant 32-bits of physical address (only if physical mapping needed)
nx_ip_driver_status	Completion status. If the driver is not able to send the packet, it will return a non-zero error status.

Packet Broadcast

This request is almost identical to the send packet request. The only difference is that the destination physical address fields are set to the Ethernet broadcast MAC address. The following NX_IP_DRIVER members are used for the packet broadcast request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_PACKET_BROADCAST
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_packet	Pointer to the packet to send
nx_ip_driver_physical_address_msw	0x0000FFFF (broadcast)
nx_ip_driver_physical_address_lsw	0xFFFFFFFF (broadcast)

NX_IP_DRIVER member	Meaning
nx_ip_driver_interface	Pointer to the interface instance.
nx_ip_driver_status	Completion status. If the driver is not able to send the packet, it will return a non-zero error status.

ARP Send

This request is also similar to the IP packet send request. The only difference is that the Ethernet header specifies an ARP packet instead of an IP packet, and destination physical address fields are set to MAC broadcast address. The following NX_IP_DRIVER members are used for the ARP send request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_ARP_SEND
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_packet	Pointer to the packet to send
nx_ip_driver_physical_address_msw	0x0000FFFF (broadcast)
nx_ip_driver_physical_address_lsw	0xFFFFFFFF (broadcast)
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to send the ARP packet, it will return a non-zero error status.

i

If physical mapping is not needed, implementation of this request is not required.

ARP Response Send

This request is almost identical to the ARP send packet request. The only difference is the destination physical address fields are passed from the IP instance. The following NX_IP_DRIVER members

are used for the ARP response send request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	<code>NX_LINK_ARP_RESPONSE_SEND</code>
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_packet</code>	Pointer to the packet to send
<code>nx_ip_driver_physical_address_msw</code>	Most significant 32-bits of physical address
<code>nx_ip_driver_physical_address_lsw</code>	Least significant 32-bits of physical address
<code>nx_ip_driver_interface</code>	Pointer to the interface instance
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to send the ARP packet, it will return a non-zero error status.

If physical mapping is not needed, implementation of this request is not required.

RARP Send

This request is almost identical to the ARP send packet request. The only differences are the type of packet header and the physical address fields are not required because the physical destination is always a broadcast address.

The following `NX_IP_DRIVER` members are used for the RARP send request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	<code>NX_LINK_RARP_SEND</code>
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_packet</code>	Pointer to the packet to send
<code>nx_ip_driver_physical_address_msw</code>	0x0000FFFF (broadcast)
<code>nx_ip_driver_physical_address_lsw</code>	0xFFFFFFFF (broadcast)

NX_IP_DRIVER member	Meaning
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to send the RARP packet, it will return a non-zero error status.

Applications that require RARP service must implement this command.

Multicast Group Join

This request is made with the ***nx_igmp_multicast_interface_join*** service. The network driver takes the supplied multicast group address and sets up the physical media to accept incoming packets from that multicast group address. Note that for drivers that don't support multicast filter, the driver receive logic may have to be in promiscuous mode. In this case, the driver may need to filter incoming frames based on destination MAC address, thus reducing the amount of traffic passed into the IP instance. The following NX_IP_DRIVER members are used for the multicast group join request.

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_MULTICAST_JOIN
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_physical_address_msw	Most significant 32-bits of physical multicast address
nx_ip_driver_physical_address_lsw	Least significant 32-bits of physical multicast address
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to join the multicast group, it will return a non-zero error status.

**Multicast Group
Leave**

This request is invoked by explicitly calling the ***nx_igmp_multicast_leave*** service. The driver removes the supplied Ethernet multicast address from the multicast list. After a host has left a multicast group, packets on the network with this Ethernet multicast address are no longer received by this IP instance. The following NX_IP_DRIVER members are used for the multicast group leave request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	NX_LINK_MULTICAST_LEAVE
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_physical_address_msw</code>	Most significant 32 bits of physical multicast address
<code>nx_ip_driver_physical_address_lsw</code>	Least significant 32 bits of physical multicast address
<code>nx_ip_driver_interface</code>	Pointer to the interface instance
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to leave the multicast group, it will return a non-zero error status.

Attach Interface

This request is invoked from the NetX to the device driver, allowing the driver to associate the driver instance with the corresponding IP instance and the physical interface instance within the IP. The following NX_IP_DRIVER members are used for the attach interface request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	NX_LINK_INTERFACE_ATTACH
<code>nx_ip_driver_ptr</code>	Pointer to IP instance

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_interface</code>	Pointer to the interface instance.
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to detach the specified interface to the IP instance, it will return a non-zero error status.

Detach Interface

This request is invoked by NetX to the device driver, allowing the driver to disassociate the driver instance with the corresponding IP instance and the physical interface instance within the IP. The following NX_IP_DRIVER members are used for the attach interface request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	NX_LINK_INTERFACE_DETACH
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_interface</code>	Pointer to the interface instance.
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to attach the specified interface to the IP instance, it will return a non-zero error status.

Get Link Status

The application can query the network interface link status using the NetX service ***nx_ip_interface_status_check*** service for any interface on the host. See Chapter 4, “Description of NetX Services” on page 107, for more details on these services.

The link status is contained in the *nx_interface_link_up* field in the NX_INTERFACE structure pointed to by *nx_ip_driver_interface* pointer. The following NX_IP_DRIVER members are used for

the link status request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	<code>NX_LINK_GET_STATUS</code>
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_return_ptr</code>	Pointer to the destination to place the status.
<code>nx_ip_driver_interface</code>	Pointer to the interface instance
<code>nx_ip_driver_status</code>	Completion status. If the driver is not able to get specific status, it will return a non-zero error status.

***i** `nx_ip_status_check` is still available for checking the status of the primary interface. However, application developers are encouraged to use the interface specific service: `nx_ip_interface_status_check`.*

Get Link Speed

This request is made from within the `nx_ip_driver_direct_command` service. The driver stores the link's line speed in the supplied destination. The following `NX_IP_DRIVER` members are used for the link line speed request:

NX_IP_DRIVER member	Meaning
<code>nx_ip_driver_command</code>	<code>NX_LINK_GET_SPEED</code>
<code>nx_ip_driver_ptr</code>	Pointer to IP instance
<code>nx_ip_driver_return_ptr</code>	Pointer to the destination to place the line speed

NX_IP_DRIVER member	Meaning
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to get speed information, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

Get Duplex Type

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver stores the link’s duplex type in the supplied destination. The following NX_IP_DRIVER members are used for the duplex type request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_GET_DUPLEX_TYPE
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_return_ptr	Pointer to the destination to place the duplex type
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to get duplex information, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

Get Error Count

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver stores the link’s error count in the supplied

destination. To support this feature, the driver needs to track operation errors. The following NX_IP_DRIVER members are used for the link error count request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_GET_ERROR_COUNT
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_return_ptr	Pointer to the destination to place the error count
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to get error count, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

Get Receive Packet Count

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver stores the link's receive packet count in the supplied destination. To support this feature, the driver needs to keep track of the number of packets received. The following NX_IP_DRIVER members are used for the link receive packet count request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_GET_RX_COUNT
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_return_ptr	Pointer to the destination to place the receive packet count
nx_ip_driver_interface	Pointer to the physical network interface
nx_ip_driver_status	Completion status. If the driver is not able to get receive count, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

**Get Transmit
Packet Count**

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver stores the link’s transmit packet count in the supplied destination. To support this feature, the driver needs to keep track of each packet it transmits on each interface. The following NX_IP_DRIVER members are used for the link transmit packet count request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_GET_TX_COUNT
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_return_ptr	Pointer to the destination to place the transmit packet count
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to get transmit count, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

**Get Allocation
Errors**

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver stores the link’s packet pool allocation error count in the supplied destination. The following NX_IP_DRIVER members are used for the link allocation error count request:

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_GET_ALLOC_ERRORS
nx_ip_driver_ptr	Pointer to IP instance

NX_IP_DRIVER member	Meaning
nx_ip_driver_return_ptr	Pointer to the destination to place the allocation error count
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to get allocation errors, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

Driver Deferred Processing

This request is made from the IP helper thread in response to the driver calling the ***nx_ip_driver_deferred_processing*** routine from a transmit or receive ISR. This allows the driver ISR to defer the packet receive and transmit processing to the IP helper thread and thus reduce the amount to process in the ISR. The ***nx_interface_additional_link_info*** field in the NX_INTERFACE structure pointed to by ***nx_ip_driver_interface*** may be used by the driver to store information about the deferred processing event from the IP helper thread context. The following NX_IP_DRIVER members are used for the deferred processing event.

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_DEFERRED_PROCESSING
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_interface	Pointer to the interface instance

User Commands

This request is made from within the ***nx_ip_driver_direct_command*** service. The driver processes the application specific user commands.

The following NX_IP_DRIVER members are used for the user command request.

NX_IP_DRIVER member	Meaning
nx_ip_driver_command	NX_LINK_USER_COMMAND
nx_ip_driver_ptr	Pointer to IP instance
nx_ip_driver_return_ptr	User defined
nx_ip_driver_interface	Pointer to the interface instance
nx_ip_driver_status	Completion status. If the driver is not able to execute user commands, it will return a non-zero error status.

This request is not used internally by NetX so its implementation is optional.

Unimplemented Commands

Commands unimplemented by the network driver must have the return status field set to NX_UNHANDLED_COMMAND.

Driver Output

All previously mentioned packet transmit requests require an output function implemented in the driver. Specific transmit logic is hardware specific, but it usually consists of checking for hardware capacity to send the packet immediately. If possible, the packet payload (and additional payloads in the packet chain) are loaded into one or more of the hardware transmit buffers and a transmit operation is initiated. If the packet won't fit in the available transmit buffers, the packet should be queued, and be transmitted when the transmission buffers become available.

The recommended transmit queue is a singly linked

list, having both head and tail pointers. New packets are added to the end of the queue, keeping the oldest packet at the front. The `nx_packet_queue_next` field is used as the packet's next link in the queue. The driver defines the head and tail pointers of the transmit queue.

Because this queue is accessed from thread and interrupt portions of the driver, interrupt protection must be placed around the queue manipulations.

Most physical hardware implementations generate an interrupt upon packet transmit completion. When the driver receives such an interrupt, it typically releases the resources associated with the packet just being transmitted. In case the transmit logic reads data directly from the `NX_PACKET` buffer, the driver should use the **`nx_packet_transmit_release`** service to release the packet associated with the transmit complete interrupt back to the available packet pool. Next, the driver examines the transmit queue for additional packets waiting to be sent. As many of the queued transmit packets that fit into the hardware transmit buffer(s) are de-queued and loaded into the buffers. This is followed by initiation of another send operation.

As soon as the data in the `NX_PACKET` has been moved into the transmitter FIFO (or in case a driver supports zero-copy operation, the data in `NX_PACKET` has been transmitted), the driver must move the `nx_packet_prepend_ptr` to the beginning of the IP header before calling **`nx_packet_transmit_release`**. Remember to adjust `nx_packet_length` field accordingly. If an IP frame is made up of multiple packets, only the head of the packet chain needs to be released.

Driver Input

Upon reception of a received packet interrupt, the network driver retrieves the packet from the physical hardware receive buffers and builds a valid NetX packet. Building a

valid NetX packet involves setting up the appropriate length field and chaining together multiple packets if the incoming packet's size is greater than a single packet payload. Once properly built, the `prepend_ptr` is moved after the physical layer header and the receive packet is dispatched to NetX.

NetX assumes that the IP and ARP headers are aligned on a ULONG boundary. The NetX driver must, therefore, ensure this alignment. In Ethernet environments this is done by starting the Ethernet header two bytes from the beginning of the packet. When the `nx_packet_prepend_ptr` is moved beyond the Ethernet header, the underlying IP or ARP header is 4-byte aligned.

There are several receive packet functions available in NetX. If the received packet is an ARP packet, `_nx_arp_packet_deferred_receive` is called. If the received packet is an RARP packet, `_nx_rarp_packet_deferred_receive` is called. There are several options for handling incoming IP packets. For the fastest handling of IP packets, `_nx_ip_packet_receive` is called. This approach has the least overhead, but requires more processing in the driver's receive interrupt service handler (ISR). For minimal ISR processing `_nx_ip_packet_deferred_receive` is called.

After the new receive packet is properly built, the physical hardware's receive buffers are setup to receive more data. This might require allocating NetX packets and placing the payload address in the hardware receive buffer or it may simply amount to changing a setting in the hardware receive buffer. To minimize overrun possibilities, it is important that the hardware's receive buffers have available buffers as soon as possible after a packet is received.

i

The initial receive buffers are setup during driver initialization.

Deferred Receive Packet Handling

The driver may defer receive packet processing to the NetX IP helper thread. For some applications this may be necessary to minimize ISR processing as well as dropped packets.

To use deferred packet handling, the NetX library must first be compiled with ***NX_DRIVER_DEFERRED_PROCESSING*** defined. This adds the deferred packet logic to the NetX IP helper thread. Next, on receiving a data packet, the driver must call `_nx_ip_packet_deferred_receive()`:

```
_nx_ip_packet_deferred_receive(ip_ptr, packet_ptr);
```

The deferred receive function places the receive packet represented by `packet_ptr` on a FIFO (linked list) and notifies the IP helper thread. After executing, the IP helper repetitively calls the deferred handling function to process each deferred packet. The deferred handler processing typically includes removing the packet's physical layer header (usually Ethernet) and dispatching it to one of these NetX receive functions:

```
_nx_ip_packet_deferred_receive
_nx_arp_packet_deferred_receive
_nx_rarp_packet_deferred_receive
```

Example RAM Ethernet Network Driver

The NetX demonstration system is delivered with a small RAM-based network driver, defined in the file ***nx_ram_network_driver.c***. This driver assumes the IP instances are all on the same network and simply assigns virtual hardware addresses (MAC addresses) to each device instance as they are created. This file provides a good example of the basic structure of NetX physical network drivers. Users may develop their own network drivers using the driver framework presented in this example.

The entry function of the network driver is `_nx_ram_network_driver()`, which is passed to the IP instance create call. Entry functions for additional network interfaces can be passed into the `nx_ip_interface_attach()` service. After the IP instance starts to run, the driver entry function is invoked to initialize and enable the device (refer to the case **NX_LINK_INITIALIZE** and **NX_LINK_ENABLE**). After the **NX_LINK_ENABLE** command is issued, the device should be ready to transmit and receive packets.

The IP instance transmits network packets via one of these commands:

<code>NX_LINK_PACKET_SEND</code>	An IP packet is being transmitted,
<code>NX_LINK_ARP_SEND</code>	An ARP request or ARP response packet is being transmitted,
<code>NX_LINK_ARP_RARP_SEND</code>	A Reverse ARP request or response packet is being transmitted,

On processing these commands, the network driver needs to prepend the appropriate Ethernet frame header, and then send it to the underlying hardware for transmission. During the transmission process, the network driver has the exclusive ownership of the packet buffer area. Therefore once the data are being transmitted (or once the data has been copied into the driver internal transfer buffer), the network driver is responsible for releasing the packet buffer by first moving the prepend pointer past the Ethernet header to the IP header (and adjust packet length accordingly), and then by calling the `nx_packet_transmit_release()` service to release the packet. Not releasing the packet after data transmission will cause packets to leak.

The network device driver is also responsible for handling incoming data packets. In the RAM driver example, the received packet is processed by the

function ***_nx_ram_network_driver_receive()***.

Once the device receives an Ethernet frame, the driver is responsible for storing the data in NX_PACKET structure. Note that NetX assumes the IP header starts from 4-byte aligned address. Since the length of Ethernet header is 14-byte, the driver needs to store the starting of the Ethernet header at 2-byte aligned address to guarantee that the IP header starts at 4-byte aligned address.

BSD-Compatible Socket API

BSD-Compatible Socket API

The BSD-Compatible Socket API supports a subset of the BSD Sockets API calls (with some limitations) by utilizing NetX primitives underneath. IPv4 protocols and network addressing are supported. This BSD-Compatible Sockets API layer should perform as fast or slightly faster than typical BSD implementations because this API utilizes internal NetX primitives and bypasses unnecessary NetX error checking.

Configurable options allow the host application to define the maximum number of sockets, TCP maximum window size, and depth of listen queue.

Due to performance and architecture constraints, this BSD-Compatible Sockets API does not support all BSD Sockets calls. In addition, not all BSD options are available for the BSD services, specifically the following:

- ***select()*** call works with only ***fd_set*** *readfds, other arguments in this call e.g., writefds, exceptfds are not supported.
- The “int flags” argument is not supported for ***send()***, ***recv()***, ***sendto()***, and ***recvfrom ()*** calls.
- The BSD-Compatible Socket API supports only limited set of BSD Sockets calls.

The source code is designed for simplicity and is comprised of only two files, ***nx_bsd.c*** and ***nx_bsd.h***. Installation requires adding these two files to the build project (not the NetX library) and creating the host application which will use BSD Socket service calls. The ***nx_bsd.h*** file must also be included in your application source. Sample demo files are included with the distribution which is freely available with NetX. Further details are available in the help

and Readme files bundled with the BSD-Compatible Socket API package.

The BSD-Compatible Sockets API supports the following BSD Sockets API calls:

<i>INT</i>	<i>bsd_initialize (NX_IP *default_ip, NX_PACKET_POOL *default_pool, CHAR *bsd_memory_not_used);</i>
<i>INT</i>	<i>getpeername(INT sockID, struct sockaddr *remoteAddress, INT *addressLength);</i>
<i>INT</i>	<i>getsockname(INT sockID, struct sockaddr *localAddress, INT *addressLength);</i>
<i>INT</i>	<i>recvfrom(INT sockID, CHAR *buffer, INT buffersize, INT flags, struct sockaddr *fromAddr, INT *fromAddrLen);</i>
<i>INT</i>	<i>recv(INT sockID, VOID *rcvBuffer, INT bufferLength, INT flags);</i>
<i>INT</i>	<i>sendto(INT sockID, CHAR *msg, INT msgLength, INT flags, struct sockaddr *destAddr, INT destAddrLen);</i>
<i>INT</i>	<i>send(INT sockID, const CHAR *msg, INT msgLength, INT flags);</i>
<i>INT</i>	<i>accept(INT sockID, struct sockaddr *ClientAddress, INT *addressLength);</i>
<i>INT</i>	<i>listen(INT sockID, INT backlog);</i>
<i>INT</i>	<i>bind (INT sockID, struct sockaddr *localAddress, INT addressLength);</i>
<i>INT</i>	<i>connect(INT sockID, struct sockaddr *remoteAddress, INT addressLength);</i>
<i>INT</i>	<i>socket(INT protocolFamily, INT type, INT protocol);</i>
<i>INT</i>	<i>soc_close (INT sockID);</i>
<i>INT</i>	<i>select(INT nfds, fd_set *readfds, fd_set *writefds, fd_set *exceptfds, struct timeval *timeout);</i>
<i>VOID</i>	<i>FD_SET(INT fd, fd_set *fdset);</i>
<i>VOID</i>	<i>FD_CLR(INT fd, fd_set *fdset);</i>
<i>INT</i>	<i>FD_ISSET(INT fd, fd_set *fdset);</i>
<i>VOID</i>	<i>FD_ZERO(fd_set *fdset);</i>
